Abstract

At the March 2012 Intersessional meeting of the AWMP Working Group in La Jolla, CA, a set of trials was agreed upon for consideration as part of the Eastern Pacific Gray Whale Implementation Review. Since then, progress has been made on conditioning that set of trials. An assessment of the preliminary conditioning results is presented here, with a focus on five trials that were not able to mimic the available data as well as the remaining trials. If any of these five trials is to be dropped from further consideration, there must be unanimous agreement within the Working Group for such.

Background and Methods

The set of trials agreed upon at the March 2012 Intersessional meeting is outlined in Tables 1 and 2 (trials requiring conditioning have a 'Y' in the second column of those tables). The preliminary conditioning runs were completed by Punt. A small group, consisting of Punt, Scordino and Brandon then conducted an initial evaluation to determine the adequacy of the conditioning for each trial.

The primary factor assessed during this process was the extent to which each trial was able to mimic the observed patterns in the time series of PCFG abundance estimates (all of the trials were able to mimic the abundance estimates for the northern stock). Additionally, the posterior distributions for the parameters of the two-stock population dynamics model were examined to identify trials where the default range for certain priors needed to be adjusted.

Once Punt, Scordino and Brandon had agreed on a set of trials that deserved further scrutiny, Butterworth and Donovan then evaluated the preliminary conditioning results for those trials. Only trials that all five authors agreed deserved attention by the larger group are submitted here as potential trials to be dropped.

Results and Discussion

Results of the preliminary round of conditioning are available via the AWMP DropBox in the DiagnosticPlots2 directory (or via email from the contact author). The vast majority of trials was deemed to have been conditioned satisfactorily.

PCFG carrying capacity was the only parameter for which the bounds on the prior were found to be too restrictive for certain trials. For those trials that were unable to mimic the PCFG abundance estimates, several exhibited posterior distributions for PCFG carrying capacity that appeared to be piling up against the default upper bound (500). Those trials were hence re-conditioned after increasing the upper bound of the prior on this parameter to 1000, and then re-evaluated based on the updated runs. Depending on the scenario, these larger upper values were large enough that: (a) the scenario in question was able to mimic the abundance estimates; or (b) it became

obvious that further increases in this upper bound would make no substantial difference to the model trajectories.

After this process, five trials were identified for potential exclusion:

- (i) B02C;
- (ii) I02C;
- (iii) P05A;
- (iv) P14B; and
- (v) P58B (robustness trial 8B).

Comparisons of model trajectories and PCFG abundance estimates for these trials are shown in Figures 1-3. When evaluating the adequacy of these five trials, it may be helpful to compare those to a trial which was assessed to be representative of a category of fit one notch better, *e.g.* trial I05A (Fig 4).

There were some questions about the adequacy of trial I05A. However, it is able to mimic the initial increase in abundance estimates, even though the model trajectory is systematically lower than the estimates in more recent years. For comparison, trial I02C (Fig 1. Right panel), is also able to mimic the initial increase in abundance, but the model trajectory in recent years is even lower than that for I05A. Trials P14B and P58B (Fig. 3) are able to mimic the abundance estimates in recent years, but do not mimic the initial increase very well. Trial P05A is not able to mimic either the initial increase or the recent abundance estimates.

There is something of a gradient in the ability of the trials to mimic the data. This presents a challenge in identifying a cut-off point for rejecting trials as implausible. We have identified several trials that represent the lower end of the plausibility spectrum, based on their relative inability to mimic the PCFG abundance estimates. However, if any of these five trials is to be dropped from further consideration, there must be unanimous agreement within the Working Group for such.

Table 1

The *Evaluation Trials*. Values given in bold type show differences from the base case trial. The final four columns indicate which trials apply to which 'broad' hypotheses. For 'broad' hypotheses B and I, the number given is the plus in 1999/2000. Note that operating models based on hypotheses P do not fit to the 1998 abundance estimate for the PCFG. Base-case $\Phi = 0.3$

Trial	Condition	Description	$MSYR_{1+}$	$MSYR_{1+}$	Final Need	Annual Immigration	Survey freq.	Survey Bias (North)	Hypothesis		
			North	PCFG					P	B	I
1A	Y	$MSYR_{1+} = 4.5\%/4.5\%$	4.5%	4.5%	340 / 7	2	10 / 1	1	20*	Y*	10
