Annex K

Report of the Standing Working Group on Environmental Concerns

Members: Rojas-Bracho (Chair), Baba, Bass, Berggren, Bjørge, Brownell, Cha, Charrassin, Collins, Cozzi, Dinter, Engel, Ensor, Findlay, Fortuna, Fujise, Gales, Gedamke, Gong, Groch, Gronvik, Hatanaka, Hung, Hyun Woo, Ilyashenko, Iñíguez, Iwasaki, Jung, Youn, Kawahara, Kim, D.N., Kim, S.G., Kim, S.W., Kim, Z.G., Kock, Krahn, Lawrence, Lens, Mae, Magloire, Matsuoka, Mattila, Moore, Mori, Morishita, Murase, Nishiwaki, Northridge, O'Hara, Ohta, Olafdottir, Palazzo, Palka, Pamplin, Panigada, Parsons, Pinto de Lima, Pomilla, Porter, Punnett, Rambally, Reijnders, Ridoux, Ritter, Rogan, Rose, Rosenbaum, Rowles, Sadler, Secchi, Senn, Shimada, Simmonds, M., Sironi, Smith, Soh, Sohn, Song, Stachowitsch, Suydam, Thiele, Tominaga, Urban, Van Waerebeek, Víkingsson, Vladimirov, Walters, Weinrich, Williams, Wilson, Yamakage, Yasokawa, Yoshida, Zenitani, Zerbini, Zhu.

1. CONVENOR'S OPENING REMARKS

Rojas-Bracho welcomed the participants, especially those who attended the sea ice mini-symposium.

2. ELECTION OF CHAIR

Rojas-Bracho was elected Chair.

3. APPOINTMENT OF RAPPORTEURS

O'Hara and Williams were appointed rapporteurs.

4. ADOPTION OF AGENDA

The adopted Agenda is given as Appendix 1.

5. REVIEW OF AVAILABLE DOCUMENTS

The following documents were relevant to the Standing Working Group (SWG): SC/57/E1-16; BRG1, 3; IA6, 7, 20; O21; SH4; SM1,2; WW1,3,5.

6. SEA ICE AND WHALE HABITAT: A JOINT SPECIAL PRE-MEETING SESSION WITH THE IN-DEPTH ASSESSMENT (IA) AND BOWHEAD, RIGHT AND GRAY (BRG) SUB-COMMITTEES

At its 2004 meeting, the Scientific Committee (SC) agreed that a proposal for a joint Symposium (IA, BRG and E sub-committees) to review current knowledge of polar sea ice environments and variability with relevance to cetaceans should be given high priority. The joint sea ice Symposium 'High Latitude Sea Ice Environments: Effects on Cetacean Abundance, Distribution and Ecology' (hereafter referred to as the Sea Ice Symposium) was hosted by the Environmental Concerns SWG as a pre-meeting (28-29 May 2005, Ulsan, Republic of Korea) to the main SC meeting. The aim of the Symposium was to review information on sea ice environments in the Arctic and Antarctic, and to develop means of incorporating sea ice and similar data into analyses and models used by the SC in its work.

Moore and Thiele presented an overview of the Sea Ice Symposium report (SC/57/Rep5) to a joint session of the E, BRG and IA sub-committees. Overall, the symposium provided an excellent means for scientists that typically work at either pole to meet and exchange information on sea ice variability with respect to whale habitats. The three Invited Participants (IPs) provided a foundation of understanding of decadal changes and current conditions at both poles, which the Convenors here wish to again acknowledge with gratitude. Themes common to all IP presentations included: (1) the extreme variability in sea ice conditions at both poles; (2) the complexity of both polar ecosystems; and (3) the great dearth of sea ice data, especially at scales relevant to cetacean habitat assessment. Research tools are now available that can augment future studies at both poles, including: (1) passive acoustic recorders, both short and long-term instruments (i.e. sonobuoys and moored recorders); (2) satellite telemeters for attachment to cetaceans, augmented with oceanographic instrumentation (e.g. conductivity, temperature and depth (CTD), flurometers); and (3) sea ice analytical tools to provide routine application at the temporal and spatial scale of whale habitats (i.e., days to months; 1 to 1,000s of kilometres). The SWG **strongly recommended** the application of these tools to future cetacean research in the Arctic and Antarctic and that researchers seek means to continue the collaborative exchange initiated at the symposium.

High priority intersessional projects were identified jointly by Symposium participants from the E, IA and BRG sub-committees. The Arctic sea ice working group proposed two projects for intersessional work. The first is focused on retrospective analyses of sea ice conditions, using both satellite-derived data and traditional ecological knowledge (TEK) to collate with extant records of Bering-Chukchi-Beaufort (B-C-B) bowhead and Eastern North Pacific (ENP) gray whale (*Eschrichtius robustus*) population dynamics. The second project seeks to investigate health status in both populations, with regard to variability in sea ice. The Antarctic projects focus on: (1) areas of high minke whale density (*Balaenoptera* sp.); (2) shelf break position correlate with whale distribution; (3) data rich regional comparison of variables affecting distribution; (4) analysis

of minke whale distribution and relative proportions inside and outside the pack ice; (5) integrating historical and recent whale catch/sighting data; and (6) support for the completion of the Southern Ocean Collaboration (SOC) Database. The Antarctic Working Group identified a core set of six analysis projects from the initial focus questions for the Antarctic group. Analysis projects were considered on the basis of: (1) availability of whale and environmental data series at appropriate scales, (2) relevance to the work of IA and E sub-committees, (3) potential to contribute towards resolving high priority issues in the SC, and (4) interest and willingness of invited experts and symposium participants to provide data series and conduct the work intersessionally. The joint E/IA funding request is given in Appendix 4. The SWG also requests funding to continue its core work conducted under the IWC SOC Working Group (IWC/SOC WG) for IWC collaboration on the two final SO-GLOBEC cruises and support for Thiele for coordination, analysis and development of IWC as a core component of ICCED (joint E/BRG, E/IA and E funding requests are in Appendix 4).

Finally, it was noted that the Integrated Analysis of Circumpolar Ecosystem Dynamics (ICCED) initiative in the Southern Ocean and the International Polar Year (IPY) afford unprecedented opportunities for collaborative multi-disciplinary research in polar regions. The aforementioned tools provide the means to fully integrate cetacean studies into broad-scale programmes of marine ecosystem research in ways unimaginable only a few years ago. For these reasons, the SWG **strongly recommended** urgent attention to integration of cetacean research in the upcoming polar research (ICCED and IPY).

The SWG expressed their deep appreciation to Thiele and Moore for their hard work in organising and convening the Sea Ice Symposium. The SWG **strongly endorsed** the findings and recommendations in the report of the Symposium.

7. REVIEW OF THE REPORT OF THE HABITAT DEGRADATION WORKSHOP

Simmonds (the Workshop Convenor) presented the Report of the IWC Workshop on Habitat Degradation (HD) which was held at the Certosa di Pontignano, University of Siena, 12-15 November, 2004. The full report, including a list of participants is given in SC/57/Rep2. The Workshop was made possible by the financial support of the Government of Austria, the Environmental Investigation Agency, ASMS-Ocean Care and the World Wide Fund for Nature. Simmonds thanked the IWC Secretariat and Cristina Fossi and Stefania Ancora of the University of Siena for their logistical support and Greg Donovan for his work to finalise the Workshop report. He noted that Steve Reilly was the meeting chair, with Clare Perry as primary rapporteur.

Simmonds outlined the material reviewed by the Workshop and the discussions that ensued. He noted in particular the report of the Workshop Scoping Group meeting, which occurred in Rome in 2001 and the key papers provided by Moore, Ragen, Reijnders, Taylor, Cañadas, Bjørge, Lusseau and Parsons (a full list is given in SC/57/Rep2). These led to consideration of the kinds of modelling approaches that might be applied and these are summarised here in a framework given in Fig. 1. The main recommendations of the Workshop were highlighted.

The Workshop agreed that:

(1) First attempts should be made to apply the framework to specific case studies. Case studies identified as initially promising include bottlenose dolphins (*Tursiops* sp.) from Florida, harbour porpoises (*Phocoena phocoena*) from Europe, and resident killer whales (*Orcinus orca*) from the northwest coast of North America. This will enable further development of the framework, and give a clearer idea of where data and methodological gaps exist.
(2) Effort should be made to further develop methodological approaches to distinguish the relative effects of different stressors via population and spatial modelling approaches.
(3) Consideration be given to applying the framework for one area, and then using the results to make predictions for the same species in a different area and comparing this with the actual situation as a type of 'validation'. A similar approach has been successfully used with spatial modelling techniques to try to determine whether it is reasonable to predict cetacean distribution in areas where data are not available.
(4) A follow-up Workshop to take place at an appropriate time to review the progress of this work plan, make specific progress on the analysis of data (e.g. porpoise or bottlenose dolphin case studies) and make recommendations for future work.

The Workshop strongly recommended that effort be put into further consideration of the framework given in Fig. 1 including: (1) the linking of the different types of models, e.g. through data on vital rates; (2) developing ways to model how stressors affect features of the habitat or individuals directly; and (3) developing ways in which spatial modelling approaches can better incorporate dynamic variables. Such a modelling framework will be valuable in focussing studies to model existing data and in directing future analytical and modelling work. Attention must also be given to trying to determine the relative importance of natural versus anthropogenic environmental changes on the dynamics of cetacean populations.

The Workshop strongly recommended the continuation (and where necessary, initiation) of long-term studies both of cetaceans and key biotic and abiotic features of the environment. In this regard, it recognised that this may require a change in emphasis of both management and research agencies. In the present climate there is often reluctance to invest in long-term programmes. The Workshop stressed that the issue of cetaceans and habitat degradation will only be resolved by long-term multidisciplinary datasets. To accomplish these will require a change in the way many institutes evaluate scientists. At present, evaluation is often on the basis of the number of publications. It is often a feature of long-term monitoring programmes that they do not result in several publications per year despite the fundamental importance of the work. This paradigm may discourage high calibre scientists from committing to such programmes to the detriment of cetacean conservation science.

The Workshop also recognised the difficulties in developing (and measuring) suitable indices both of habitat quality and response in cetaceans. It recommended that further work be undertaken in this regard particularly with respect to:

(1) identifying key features of cetacean habitat;
(2) reviewing methods used to assess cetacean nutritive status in both live and dead specimens, with a view to future standardisation of techniques; and
(3) developing indices of cetacean response to various stressors.

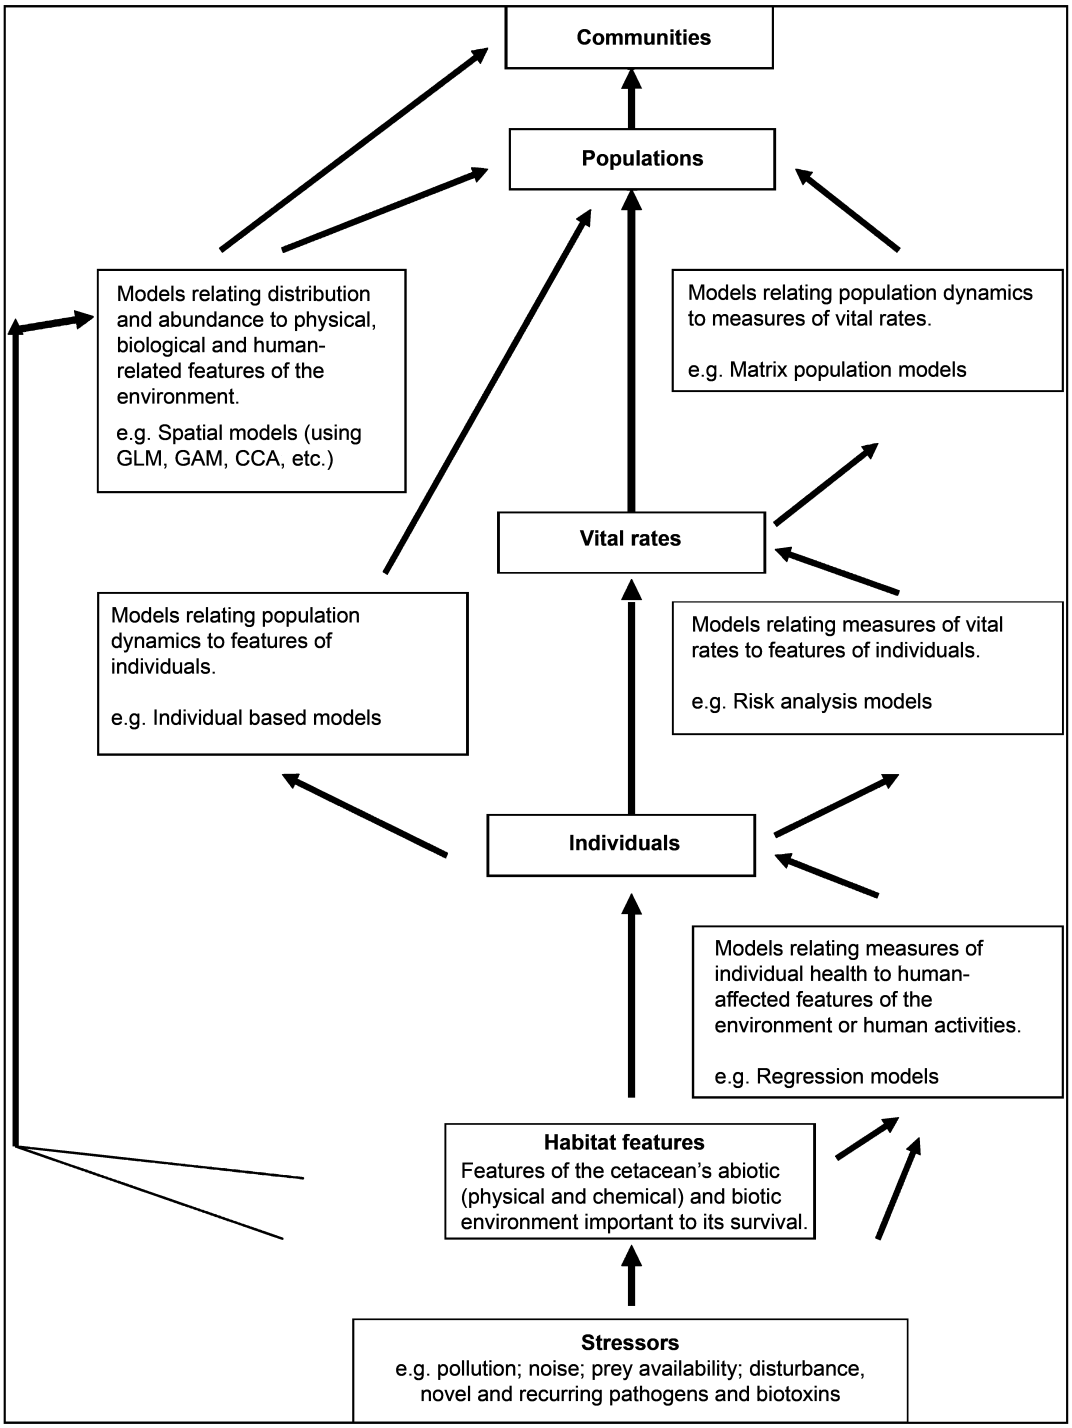

Fig. 1. General framework for modelling the links between environmental stressors that degrade habitat and population effects.

Both (1) and (3) will require a better understanding of the feeding and reproductive behaviour of cetaceans. The Workshop recommended that fine-scale feeding studies such as those recommended by the SOWER 2000 Workshop be undertaken. It also recommended**,** where appropriate, studies using satellite tags that can also record environmental variables. The Workshop also recommended further work to develop standardised behavioural sampling techniques and indices that will allow inter-site comparisons, as well as the integration of behavioural indices to the framework.

The SWG **endorsed** the recommendations of the Workshop report in general. The Chair thanked Simmonds for his thorough report and its summary. One member noted that there were repeated discussions of natural versus anthropogenic change, likening this approach to the difficulty with studies on Prudhoe Bay, Alaskan oil industry impacts on caribou herd size (abundance) and dynamics (migration and calving grounds) and teasing apart the impacts of natural variability from anthropogenic oil industry activities. Some anthropogenic impacts are obvious by nature: low pipes that block animal movements are easy to detect and fix. But it was cautioned that the more subtle effects have challenged researchers in this area despite 30 years of research (on a species that is logistically easier to study than cetaceans), and emphasised to members that assessing the impact of anthropogenic habitat degradation on wildlife populations is not easy. However, he welcomed the approach outlined in the Workshop report.

It was pointed out that for the purposes of following long-term ecosystem changes, grey literature has strong value, as does properly archiving older studies and datasets, which can help ensure continuity. One member strongly concurred, and noted that in some policy fora, including the US Marine Mammal Commission Federal Advisory Committee on acoustic impacts on marine mammals, there is an over-emphasis on peer-reviewed published literature. However, it was also noted that there is a current trend toward funding archiving of older datasets, including acoustic information.

One member expressed initial scepticism of the outcomes of the HD Workshop, primarily because it would be conceptually and logistically challenging to consider simultaneously such diverse factors as *inter alia*, sea ice, pollution, prey availability and noise. Each component individually would be difficult to handle, and a holistic approach would be challenging. However, he concluded that the outcome of the Workshop offered a way forward (see Fig. 1) to discriminate between biological effects caused by HD and natural variation.

Several members endorsed the suggestion that case studies be used to assess the feasibility of being able to detect effects of habitat degradation on cetaceans. Some members felt that case studies should cover a variety of species and habitats – perhaps one temperate case study, plus one in polar or equatorial regions. Pinniped and terrestrial studies could be instructive as well. The SWG's attention was drawn to fig. 2 in SC/57/Rep2, and it was noted that there are already cases with fully degraded ecosystems (e.g. 'dead zones' in the Gulf of Mexico), that could allow researchers to investigate the importance of certain habitat factors. It was suggested that application of case studies to the framework should be reviewed at the 2008 SC meeting. The SWG **agreed** to keep HD on its agenda, to solicit relevant contributions for future meetings and to consider this for a formal review at the 2008 meeting.

It was noted that noise is not currently incorporated into complex HD models. Moreover, there are currently only a very few stranding monitoring schemes worldwide that look for acoustically induced trauma in their standard procedures. Despite beaked whales being regarded as especially susceptible to atypical mass strandings related to military sonar exercises, there have also been other cetacean species involved in atypical mass strandings or atypical behaviour linked to the use of military sonar (e.g. melon-headed whales (*Peponocephala electra*), short-finned pilot whales (*Globicephala macrorhynchus*), minke whales, pygmy sperm whales (*Kogia breviceps*) (Appendix 2)). The SWG stressed the importance of extending the standard scope of stranding monitoring schemes worldwide to examine pathological indicators of acoustically induced trauma in order in order to recognise and address the magnitude of problems related to naval sonar and other high-intensity underwater sound sources.

The SWG noted that this request for extension of stranding monitoring is a refinement of recommendations that have already been made, but that reiteration of this recommendation is warranted. A call for improved pathologic examination of stranded animals worldwide was appropriate in order to motivate pathologists to be more vigilant in seeking noise impact markers for cetaceans. A modification was proposed to make this recommendation more specific. Pathological information should be collected on 'typical' strandings so that their histopathology lesions can be compared to that more directly linked to acoustic trauma. New Zealand, Japan and the USA were highlighted as areas where the vast majority of 'typical' beaked whale strandings occur. Over 300 strandings of beaked whales in Japan and New Zealand have been recorded in the last 15 years (R. Brownell, pers. comm.). New Zealand is the area that has the most common (typical mass) strandings in the presumed absence of military sonar activities or similar noise exposure.

In investigations of military sonar-related strandings, there has been a dearth of full suite comparative data from 'normal strandings'. Protocols need to be systematic, regardless of whether sound-producing activities are suspected. If there is 'bias' in pathology sampling studies depending on whether the mortality is suspected to be linked to sound events, then our power to detect actual sound-related impacts becomes limited (due to lack of controls). Standardised protocols including full pathology suites are key. A recommendation from this SWG would help leverage cooperation from strandings networks in other parts of the world. With regards to ear histology, the costs are daunting, which makes analysis cost-prohibitive in most cases. Conducting full histopathology analysis of each ear costs USD$4,000 and takes 14 months. It is simply not possible to look at every ear. Nevertheless, ears should be collected, and computerised tomography (CT) scans and histopathology performed when indicated using appropriate controls. Others supported this idea, but stressed that efforts outside the USA may not be as complete and encouraged extension of ongoing studies to include these protocols elsewhere.

It was pointed out that there are less expensive methods to collect related data. For example, gas and fat embolisms could be examined from very fresh specimens from Japan and New Zealand (using Japan as a 'control' for single strandings and New Zealand as a 'control' for mass and single strandings). The key is that pathology should not be examined only in cases where noise trauma is suspected; 'controls' are needed to compare with such cases. The SWG **agreed** that management agencies and people collecting data and samples from stranded beaked whales all follow the same rigorous protocols. The SWG **encouraged** funding agencies to assist with the development of programmes to collect these data from beaked whales using rigorous protocols in the 'control' areas.

8. HABITAT RELATED ISSUES

8.1 Steering group report on POLLUTION 2000+

SC/57/E12 presented an interim report on POLLUTION 2000+: 2004-05. Reijnders indicated that three papers presented to the SC last year have been published in scientific journals and another is in review.

The Steering Group (SG) has made progress on the process of identifying a relatively highly polluted area inhabited by bottlenose dolphins. Sampling bottlenose dolphins in the Mediterranean proved to be logistically too complicated in terms of cost. Bottlenose dolphins from Tampa Bay were suggested as an alternative, however organochlorine (OC) levels did not differ much from those in bottlenose dolphins from Sarasota Bay. Meanwhile, samples from bottlenose dolphins from Biscayne Bay, Florida, USA and New Brunswick, Georgia, USA have been collected by US scientists and they may provide suitable alternatives.

The SG discussed extending the sample size of harbour porpoise tissues collected under POLLUTION 2000+, by investigating retinoid levels in harbour porpoises from the UK and/or from the northeast Atlantic. Retinoids are linked to immune function and found to be decreased by OCs and therefore may be a biomarker for OC-related effects. These large collections of harbour porpoise tissue provide, *inter*

alia, the opportunity to investigate whether reduced retinoid levels may be caused by high OC-levels or whether depleted lipid reserves are responsible for high OC concentrations and low retinoid levels.

Little progress has occurred with the remaining analyses under the harbour porpoise subproject. Administrative and logistical issues (i.e. getting the required permits) obstructed the shipping of samples from the US to Europe. This is unfortunate as it prevented the SG from presenting the expected results to the SC. Moreover, these circumstances prevented the SG from drafting a comprehensive paper on the results from Phase I of POLLUTION 2000+ for critical review by the SWG and the SC this year, as well as preparing an outline for a possible continuation into Phase II.

The SWG endorsed the POLLUTION 2000+ programme and **strongly recommended** its continuation as given in the work plan.

The Chair requested clarification on immunological work being conducted outside the original POLLUTION 2000+ Steering Group. Reijnders responded that this opportunity to collaborate allowed the SG to tie into a larger body of data that has been collected and additional years of research. POLLUTION 2000+ contributed approximately two years of data. Reijnders indicated that the SG will not wait for these additional data to complete Phase I, but hoped that all results would be available for the Phase I assessment.

The Chair requested a table/list of the SG, with affiliation, and area of expertise in the next POLLUTION 2000+ progress report. This was agreed by the co-ordinator of the project. The Chair noted the difficulty in endorsing Phase II before seeing what the results are from Phase I as mentioned by Reijnders in SC/57/E12. It was **agreed** that the work of Phase I should be completed by next year's SC meeting.

8.2 Progress report on Southern Ocean Collaboration Working Group

Paper SC/57/E2 reviewed the (SOC WG) cetacean database. Intersessional work for the SOC WG included the development of an integrated database for simultaneously collected cetacean, sea ice and other data from field work conducted in collaboration with multidisciplinary research since 2001 (Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR), Southern Ocean Global Ecosystem Dynamics (SO-GLOBEC) and other collaborations). So far, cetacean sighting and effort data have been validated and entered into the database for: (1) all eight US SO-GLOBEC cruises in the Western Antarctic Peninsula (WAP); (2) one German SO-GLOBEC cruise in the WAP; (3) two US Cross Slope Exchanges at the Antarctic Slope Front (ANSLOPE) cruises in the Ross Sea; (4) one German SO-GLOBEC cruise to the Lazarev Sea fine scale study site in the Weddell Sea; and (5) eight of 16 Australian Southern Ocean Cetacean Ecosystems Program (SOCEP) cruises. Antarctic Sea Ice Process and Climate (ASPeCT) sea ice classifications (along-track and at sightings) have been completed for all cruises where these data were available, and cruise track files and maps of effort and sightings have been linked to the database. The extensive data validation process began with the original data checked against all available data and information sources from the surveys by one person, with a further random validation check by a second person. Sighting and effort data were plotted on cruise track data obtained independent of the cetacean surveys to further check the accuracy of positions. Completion of the database requires validation and entry of sighting and effort data from a number of cruises (CCAMLR 2000, SOCEP and British Antarctic Survey (BAS)) and a range of additional data fields and links of importance (e.g. photo identification records, maps of cruise tracks, records of other wildlife (biodiversity index), resightings, biopsy records, video footage, links to collaborative multidisciplinary data series contacts, photo and video logs, behaviour logs). The database is currently being used in: two US NSF SO-GLOBEC synthesis and analysis projects; modelling studies in collaboration with Eileen Hofmann; and other analysis projects under the direction of Thiele and Moore. The SOC database is already proving to be an important tool for exploring the seasonal and interannual variability in cetacean distribution in relation to physical and biological processes at local to circumpolar scales, and we expect that it will become a valuable resource in analyses to inform the development of the scientific plans for a new Antarctic multidisciplinary programme under the ICCED initiative.

This material was also presented during the Sea Ice Symposium (SC/57/Rep5) and was briefly presented here. The paper described the status of data entry, work required for completion (see budget item) and importance of this work to joint analysis projects under E and IA budget.

SC/57/E3 presented an update on the SOC WG. The IWC SOC WG outlined a proposal for future and intersessional work at IWC/56 (IWC, 2005a) to increase our focus on: (1) development of a database; (2) integrative analysis; and (3) field work in specific areas. The SOC WG participated in three research cruises during the 2004/05 season: (1) US NSF along the WAP; (2) US NSF ANSLOPE in the Ross Sea; and (3) Australian SOCEP in East Antarctica. Field work included: deployments of autonomous acoustic recorders and along track visual and acoustic survey and were conducted in collaboration with programmes where comprehensive data on physical and/or biological processes were collected simultaneously. The IWC SOC WG plans to continue participation in current national and international survey efforts in the Southern Ocean to complete the repeat survey opportunities afforded by SO-GLOBEC in 2005/06. Over the next two years it plans to focus on analysis of the existing data from this programme, and to use these analyses to assist in the development of a long-term programme of fine scale ecological studies, with regional and circum-Antarctic monitoring efforts as part of the ICCED initiative. Field work under ICCED is due to commence 2007/08 or 2008/09 once IPY activities are completed. The Southern Ocean Database is under development, and parts of this dataset are currently in use for integrative analysis under US, Australian and international collaborative projects. The SOC WG is contributing data and is involved in analysis on two US NSF SO-GLOBEC synthesis and analysis projects, in addition to the spatial analysis and modelling projects underway in collaboration with the following scientists: Hofmann and Klinck (Old Dominion University); Read and Friedlaender (Duke University); Sirovic (Scripps Institution of Oceanography); Thiele, McKay and Garcia (Deakin University); Moore and Friday (National Oceanographic and Atmospheric Administration); Stafford (University of Washington); Reilly (National Oceanographic and Atmospheric Administration); Gedamke (Australian Antarctic Division); Dalla Rosa (University of British Columbia) and Secchi (Fundação Universidade Federale do Rio Grande).

It was noted that Thiele's work in particular has been essential in bringing whale observations to these large-scale ecosystem projects. Whale visual and acoustic surveys were highlighted in a special issue of *Deep Sea Research* focusing

on the Southern Ocean ecosystem. The collaboration is producing good new science that is of interest to oceanographers, and is also resulting in new training opportunities.

SC/57/E4 described the IWC SOC WG field work during the intersessional period, which has involved collaboration with national programs conducting multidisciplinary ecosystem research in the Antarctic with ANSLOPE and SOCEP. Participation occurred on three research cruises between October 2004 and April 2005, in the Ross Sea, WAP and East Antarctica. The IWC and WDCS supported observers on one of these cruises (Ross Sea). Visual survey, sea-ice data collection, individual photo-identification and along-track passive acoustic survey were conducted on both cruises. As in the 2003/04 season, extensive sea ice information was recorded using the sea ice data collection protocols developed by the IWC SC Sea Ice Data Collection WG and based on the ASPeCT sea ice classifications. Analysis was undertaken both on board and after the voyage to determine the patterns between sea ice and whale densities in Antarctic waters. Preliminary results from these cruises are reported here and include: mapped distribution patterns of cetaceans from visual survey sighting data; species identification and positions for animals recorded on sonobuoys; and descriptions of environmental conditions observed or recorded as part of the multidisciplinary effort.

An autonomous Acoustic Recording Package (ARP) was moored for one year off the Indian Ocean sector of East Antarctica (Mawson ARP). The instrument was deployed from February 2003 to January 2004. A total of 71,557 files were analysed by automatic recognition software (spectrogram correlation) to detect 'true-blue' whale calls (SC/57/SH4). Calls were detected year round, with peak calling in autumn (April to June), with a secondary peak in November. Lowest calling rates occurred in summer (December to March) and winter (July to September). The Mawson ARP deployment has provided the first long-term recording of underwater acoustic signals in the Australian Antarctic Territory. This has allowed preliminary analysis to determine the seasonal presence of calling whales and the characteristics of their calls in this region.

It was noted that data from the Mawson ARP augments the data from the six ARPs successfully deployed off the Antarctic Peninsula as part of SO-GLOBEC (Sirovic *et al.*, 2004). The recordings are starting to provide a sense of blue whale seasonal occurrence in the Southern Ocean. The key surprise is that blue whales are occupying some Southern Ocean habitats nearly year-round.

The Chair asked if there were any specific plans for additional analyses of data from the Mawson instrument. Thiele indicated that next they will try to integrate acoustic detections with environmental factors including sea ice conditions. A behavioural and acoustic project is beginning off southern Australia, so that we may be able to interpret the acoustic data from the ARPs (where year-round behavioural studies are not possible) with broad categories of behaviour (e.g. travelling and feeding).

SC/57/E10 described passive acoustic observations conducted in conjunction with visual observations on the ANSLOPE 3 voyage, NBP0408, on the US icebreaker *RVIB Nathaniel B. Palmer* in 2004. Preliminary analysis of passive acoustic data were reported. Cetacean observations were conducted on the ANSLOPE 3 voyage, NBP 0408, on the *RVIB Nathaniel B. Palmer* between 13th October and 12th December 2004. Visual and acoustic surveys for cetaceans and other wildlife and ASPeCT sea ice habitat investigation were conducted. These studies were conducted under the IWC SC SOC programme in collaboration with the US National Science Foundation-funded ANSLOPE oceanography programme in the Ross Sea. This voyage was primarily focused on oceanographic measurements in the Ross Sea (between 132°E and 178°E). The main objective of the IWC SOC research programme was to collect data that would contribute to analyses to determine the relationships between cetacean distribution, especially Antarctic minke whales and sea ice habitat. Preliminary analyses of calls from the acoustic data collected along track (298.5 hours of recorded data, 597 files, representing 66 sonobuoy stations) revealed the presence of crabeater and Weddell seals and minke whales. Crabeater seal (*Lobodon carcinophagus*) or Weddell seal (*Leptonychotes weddelli*) vocalisations were detected at 49 sonobuoy stations (74%), and Antarctic minke whale vocalisations were putatively identified on 12 recordings (18%). After preliminary analysis, no other mysticete calls were detected and the data have yet to be analysed for odontocete vocalisations. The most common vocalisation believed to be from the minke whale was the 'five beat phrase' pulse train.

The SWG welcomed this updated information, and strongly **encouraged** continued collaboration in the Southern Ocean.

8.3 State of the Cetacean Environment Report (SOCER)

The editors of the SOCER (SC/57/E8 as Appendix 2) reminded the SWG that previous editions dealt with the Atlantic Ocean and Mediterranean Sea (in 2003) and the Pacific Ocean (in 2004). This year's edition covered the Arctic and Antarctic (polar) regions. Each region was divided into seven topics recognised as a priority by the SWG. A glossary was provided for species and technical terms reflecting that this is intended for a broad audience. The editors hope that the 130+ hours invested in SOCER's production is time that readers and users will save and benefit from.

Regarding the priority regions for this year in SOCER (polar), the editors found it necessary to present the Arctic and Antarctic/Southern Ocean separately, because each area has specific and unique environmental characteristics, threats and concerns. For example, the high input of freshwater from melting glaciers and permafrost in the Arctic and documented changes in water bodies could, theoretically, lead to the shutdown of thermohaline circulation (see the summaries of published papers in Appendix 2 for details). Further details about Arctic-specific issues are discussed under agenda Item 8.4.

In the Antarctic, major issues included the decrease in krill abundance over the past few decades and reductions in sea ice cover. This decrease of such important cetacean prey will have consequences to many Antarctic cetacean stocks. Also, compared to the Arctic region, there were noticeably fewer studies on pollutant levels in the Southern Ocean, although some specific concerns were raised, such as butyltin contamination resulting from anti-fouling paints being scraped off the hulls of icebreakers and other vessels by sea ice.

There were, however, some issues common to both polar regions, such as the concerns that cold temperatures in these areas may affect the action of polluting chemicals. Furthermore, the life history, ecology and physiology of polar-adapted organisms are such that toxic effects of contaminants may be exacerbated. Because there is a lack of data on polar ecotoxicology, this area of environmental science should perhaps be a research priority. Polar

ecosystems may also be sensitive to environmental changes due to relatively simple food chains and lower diversity of species in these areas.

Over the past year, one issue that was particularly highlighted was the overwhelming evidence for anthropogenic global warming. Some models predict further increases in the planet's temperature even if emission caps on greenhouse gases were effective immediately. This warming has already been documented to affect distribution of cetaceans, and prey species, in the North Atlantic and ecosystem changes resulting from this could be a major issue in the immediate future.

Another 'global' issue that could have major consequences to cetacean stocks is the epidemiology of diseases in marine organisms. Wide-range dispersal mechanisms of marine species, in particular, mean that disease outbreaks in the marine environment could be spread quickly, widely and would be extremely difficult, if not impossible, to control.

SOCER 2006 will address the Indian Ocean and include a robust Global section, and the report will conclude coverage of all regions in this first cycle. In addition, it will include, per the request of the IWC SC Chair, summary statistics from a selection of abstract services regarding the number of publications on cetacean ecology, life history, and other research and management issues that have been published in the preceding calendar year. These will be categorised based on study topic. In 2007, SOCER will cover all regions, but to keep the length manageable, will do so by summarising relevant research trends and highlighting a subset of major topics in each region.

Several members thanked the editors for their hard work, recognised the report's high quality, and welcomed the inclusion of summary statistics next year on published work in cetacean science. One member noted that he was surprised at the number of publications linking anthropogenic and environmental issues and problems for cetaceans. He was unaware of this until this SOCER report.

The Chair of the SWG noted the comprehensiveness of the pollution section of SC/57/E8 and that the Antarctic did not appear to be more pristine than the Arctic. The editors noted that the Antarctic has simply been less well studied than the Arctic with respect to pollution and it should not be assumed that Antarctic species are less contaminated.

The editors of SOCER asked SC members to keep SOCER in mind when conducting their own research. They noted that the SOCER is a reflection of search effort and 'availability' of journals in search engines and therefore requested that IWC SC members send the editors papers of relevance to increase the scope of the report.

8.4 Arctic issues

SC/57/E8 summarised many studies investigating pollutant levels in a variety of cetaceans in the Arctic (and their prey) such as bowhead whales, narwhals (*Monodon monoceros*), minke whales, killer whales, long-finned pilot whales (*G. melas*) and white whales (*Delphinapterus leucas*) (Appendix 2).

Some very high pollutant levels have been recorded (e.g. killer whales in Alaska and long-finned pilot whales in the Faroe Islands), and these levels have induced immune system suppression and reproductive failure in other mammalian species. Such studies refute the idea that the Arctic is a pristine environment.

The majority of persistent organic pollutants (POPs) are transported via the atmosphere (although some are transferred via oceanic waters) primarily from northwest Europe and North America, and also are transferred via snowfall. Considering this transport mechanism, concerns have been raised that increased snow and ice melting in the Arctic, due to global warming, may liberate organic pollutants into the marine environment. Some trace metals are also transported atmospherically, primarily from Europe and Asia to the Arctic.

Several new pollutants have been recorded in Arctic cetaceans (e.g. polychlorinated napthalenes, perfluorinated acids and polybrominated biphenyl ethers). The impacts of these new contaminants on the Arctic ecosystem and the health and biology of Arctic cetaceans are, as yet, unknown. In addition, levels of radioactive contamination in the Arctic, north of Norway, have doubled since 1996 and are predicted to double again by 2006. The primary sources of this radioactivity are believed to be nuclear facilities in the UK and France.

With respect to climate change, there are particular concerns about the effects of ice melt-water input into the Arctic marine environment. This input of freshwater is increasing due to global warming, and has the potential to cap thermohaline circulation in the North Atlantic, which could have catastrophic effects on marine ecosystems.

The Chair asked if these pollutants could be classified to determine which are the most 'dangerous' to cetaceans. The editors pointed out that some have reached equilibrium, while others have patchy distribution (suggesting that they are still being introduced into the environment). This might be a good 'dichotomy' to separate the two: (1) those with little or no input and homogeneous distribution; and (2) those with ongoing input and patchy or local distribution. It was noted that POLLUTION 2000+ will give information on the toxicity of polychlorinated biphenyls (PCBs) as a model compound for OCs. It was also noted that ecotoxicological research is rarely conducted in polar regions. The cold temperatures and physiology of polar-adapted species may affect the toxicity of contaminants in these regions. Research has not been conducted to assess pollutant toxicity in polar regions.

One member indicated that Antarctic samples are being collected, but that this is an unusual region of the world from which to receive tissue samples from cetaceans. Some chemicals banned in the 1970s in North America are still increasing in polar regions. The use of flame-retardants, e.g. polybrominated diphenyl ethers (PBDEs) is increasing. Killer whales in the Aleutians (Alaska) are showing Asian chemical signatures or profiles. Antarctic killer whales have relatively low levels of contaminants. It is inappropriate to generalise from mid-latitudes to either pole. Thus, studies have to be done by species and area. PBDEs may have a very different toxicology than PCBs or other OCs.

One member asked about the Antarctic killer whale ecotypes represented in the biopsy samples. Krahn replied that she has looked at fish-eating ecotypes only, but she controlled for trophic level by restricting her comparisons to samples from fish-eating killer whales in Alaska. Even after accounting for trophic level, Antarctic killer whale contaminant levels are still lower than those in Alaska. Moreover, the chemical signatures from the two populations are very different.

Caution was urged against tabling chemical compounds in order of 'toxicity' or 'danger' for cetaceans. It was pointed out that a table in the Special Issue on pollution lists chemicals of concern; but those tables do not and should not prioritise pollutants of concern (Reijnders *et al.*, 1999, table 1, p.15). Many are simply not yet studied. Several members flagged 'new and emerging compounds' as an issue of

concern that should be looked at at the 2008 meeting. The toxicologic understanding of these emerging chemicals is currently poor.

The abstracts of SC/57/E13 and SC/57/E5 appear in the Report of the Sea Ice Symposium (SC/57/Rep5) and were discussed here briefly. Both papers addressed the potential affect of variability in sea ice cover on BCB bowhead whales. In SC/57/E13, bowhead whale body condition was provisionally examined with reference to sea ice concentrations in the eastern Beaufort Sea. There was a strong positive correlation between bowhead whale body condition and reduced sea ice cover in the eastern Beaufort Sea. One suggestion is that a reduction of sea ice in the eastern Beaufort Sea may enhance feeding opportunities for bowhead whales that summer there. In SC/57/E5, trends in sea ice cover over 24 years (1979-2002) were examined for four months (March, June, September and November) for 4 large (~100,000km^2) and 12 small (~10,000km^2) habitats used by bowhead whales. Significant changes in sea ice cover were identified in eight regions, three large and five small. Bowhead whales have been observed feeding in, or oceanographic models predict prey entrainment to, each of these regions. Conversely, there was no change in sea ice cover in four small regions that represent wintertime refugia in the northern Bering Sea, nor in two regions that include the primary springtime migration corridor in the Chukchi Sea. This evaluation of sea ice cover at spatial and temporal scales linked to bowhead whale natural history provides a basis for research on specific regions critical to investigation of the effects of climate change on this pagophilic species. However, the biophysical links between reduction in sea ice, primary production and availability of food for bowheads in the Arctic is less clear than the sea ice-krill relationship in the Antarctic and requires investigation.

SC/57/BRG3 provided provisional results of a passive acoustic monitoring study northeast of Barrow, Alaska. Three autonomous recorders were moored near the shelf break in October 2003, in collaboration with a broad-scale oceanographic study (SC/57/E10), to detect calls of bowhead and gray whales. Two instruments were recovered in September 2004 and analyses revealed gray whale calls from October 2003 (deployment) through January 2004, followed by a break, then calls again detected in mid-March 2004 until the instrument failed in mid-May 2004. This surprising result indicates gray whales remained in the western Beaufort Sea through early winter 2004, with calls detected again less than three months later. Bowhead whale calls were also recorded on the instruments in autumn 2003, followed by a break, with detections again in mid-March, as would be expected given the seasonal migration of the BCB stock. Additional analyses of these data are underway and results will be collated with an analysis of 2004 sea ice conditions at the deployment site.

The Chair asked if the gray whales were moving farther north or staying longer. Moore indicated that the signal is more temporal than spatial; that is, gray whales were seen near Barrow in the 1980s, but appear to be staying longer to feed. The Chair asked about competition between bowhead and gray whales. Moore noted that since they are both capable of eating similar zooplankton (e.g. mysids and euphausiids), the potential for competition exists.

Anon. (2005) described co-ordination of International Research Programmes in the Arctic. The IPY 2007-08 and the Second International Conference on Arctic Research Planning (ICARPII) provide unprecedented opportunities for cetacean researchers to collaborate on multi-disciplinary projects in the Arctic. Research plans evolving from these programmes seek to address priority gaps in knowledge from the Arctic Climate Impact Assessment (ACIA) (see also SC/57/Rep5). The paper was provided to facilitate active participation in IPY and ICARPII planning by IWC/SC researchers, by providing contact information, web addresses and summaries of the goals of these international research programs. It was proposed that the IWC, as the recognised body for the management of whale stocks, should link formally to these ongoing research programmes. The SWG **recommended** that the IWC pursue formal ties to these international research programmes, and that participation from their oceanographers and ecologists be encouraged in whale research.

8.5 Anthropogenic noise

In 2004, the IWC's Scientific Committee '**agreed** that there is now compelling evidence implicating military sonar as a direct impact on beaked whales in particular. The Committee also agreed that evidence of increased sounds from other sources, including ships and seismic activities, were cause for serious concern' (IWC, 2005a, p.37). The Committee went on to identify increases in seismic noise and shipping as 'cause for serious concern'. It emphasised the importance of applying the precautionary principle in addressing the issue and it made a number of specific recommendations for reducing the impacts of seismic exploration. Finally, it made a commitment to return to this issue at a future meeting.

SC/57/E8 summarised scientific studies investigating noise issues, and documented major noise-related events that occurred over the past year. In particular, there have been a number of typical and 'atypical mass stranding events'[1] that have occurred coincident with use of high intensity sound sources, in particular military sonars. Such mass strandings include events in North Carolina (USA) and the Canary Islands (Spain), and published information on atypical mass strandings in the Galapagos Islands linked to seismic surveys. In addition, a 'milling'[2] event was reported in Hawaii (USA) again linked to military activities. It should be noted that although some of these events involved beaked whales, a variety of other cetacean species were involved, including minke whales.

A number of international bodies have expressed their concerns about noise, in the form of resolutions, including ASCOBANS, ACCOBAMS, the IUCN and the European Parliament. These bodies typically called for dedicated, independent research on the impacts of noise on cetaceans, echoing the recommendations made by the IWC SC in 2004, and the introduction of regulations to control noise in cetacean habitats. The European Parliament called for restrictions on the use of high intensity active sonars in European waters and a moratorium on the development of new high intensity military sonar systems – a particularly strong statement indicative of very high levels of concern.

Three other studies summarised in SOCER, although conducted on non-cetaceans, could have implications for the health of whales. The first study reported that well-fed animals showed a response to human disturbance, while animals with fewer food resources did not (Beale and

[1] An 'atypical mass stranding event' is defined for the purposes of this document as follows: 'whales mass strand at approximately the same time but not in the same location (IWC, 2005a, p.272)'.

[2] A milling event is defined for the purposes of this document as follows: 'a group of normally pelagic cetaceans enters shallow water and begins to circle continually or move about haphazardly in a tightly packed group, with an occasional member breaking away and swimming toward the beach.'

Monaghan, 2004). The second study noted that juvenile animals raised in a noisy environment displayed retarded development in auditory centres of the brain (Abe *et al.*, 2001). The third study reported that pollutants (in this case, tributyltin) can cause hearing damage (Song *et al.*, 2005).

Brownell reiterated the importance of clarity in terminology in terms of strandings. The events coincident with military sonar use have been called 'atypical mass strandings' as compared to 'typical' events (Frantzis and Cebrian, 1998). In atypical mass strandings, beaked whales strand at approximately the same time, but not in close proximity.

SC/57/E9 presented the latest in a series of updates on noise pollution that had been provided to the SC. An international workshop (13-16 April 2004, Baltimore, Maryland, USA) recently considered beaked whales and noise, including the mechanisms that might lead to noise-associated strandings. This workshop concluded that, despite the increasing number of atypical mass strandings associated with military sonar, the mechanism of injury remains unknown. It is increasingly apparent that tissue damage and strandings may be induced at lower sound levels than those that induce auditory damage (i.e., lower than those currently being used as an acceptable level for management guidance – often a received level of 180 dB re: 1μPa, or a radius of 500 metres as a 'safety zone' – e.g. the Mitigation of Seismic Noise in the Marine Environment, Statement of Canadian Practice on Seismic Surveys). The authors also noted that further evidence of decompression-type sickness in beaked whales has recently been illustrated by researchers in the Canary Islands (Arbelo *et al.*, 2005; Espinosa *et al.*, 2005; Fernández *et al.*, 2005) who provide evidence of a new atypical beaked whale mass stranding there that coincided with the international naval exercise known as 'Majestic Eagle'. This was conducted more than 100km north of the Canary Islands in July 2004. Although the whale bodies retrieved were too decomposed to allow gas embolisms to be detected, systematic fat embolisms were found in these animals. These were also characteristic of the stranded beaked whales associated with an earlier exercise, 'Neo-Tapon', in 2002. The probability that the animals associated with the 'Majestic Eagle' exercise died at sea is extremely high (Fernández *et al.* 2005). This increases the concern that other animals affected during similar events are also dying at sea but are not being discovered and examined.

With respect to mitigation issues, the authors concluded that the recent literature indicated that it is no longer realistic to limit mitigation methods to consideration of auditory impacts to within a small radius of the sound source. Other mitigation methods and approaches therefore needed to be prioritised. In addition, it was noted that Barlow and Gisiner (2006) concluded that the overall probability of detecting beaked whales during 'mitigation monitoring' is likely to be 24 to 48 times *lower* than that achieved during dedicated sighting surveys. They calculated that less than 2% of beaked whales would be detected during mitigation monitoring – if the animals were directly in the path of the ship. This detection would drop to zero by ~1km from the trackline. The recent beaked whale workshop also concluded that current monitoring and mitigation methods for beaked whales are ineffective in the detection and protection of these animals from adverse sound exposure. Barlow and Gisner (2006) also commented on the relatively early stage of development of the new detection methodologies, such as active sonar and lack of evidence of the efficacy of commonly used mitigation measures (e.g. ramp-up). Hoyt (2005) has recently provided a substantive review of Marine Protected Areas (MPAs) as they relate to cetacean conservation and the authors of SC/57/E9, building on this excellent review, suggested that appropriately managed MPAs have the potential to help address noise pollution. They also suggested that there is an urgent need to develop alternative technologies to those that currently employ or produce loud marine noise. For example, a recent symposium held on 18-19 May 2004 in Arlington, VA, USA (Southall, 2005) on shipping noise and marine mammals discussed development of ship quietening technologies. A further example is the marine vibrational device that is under development as an alternative to the use of airgun arrays in seismic survey of the seabed and which has a lower peak amplitude, slower rise time and significantly less energy above 100Hz (Smith and Jenkerson, 1998).

With respect to MPAs and noise, some SWG members noted that these might indeed be a very useful tool to reduce noise impacts on cetaceans. It was also noted that the IUCN has requested the World Commission on Protected Areas to consider noise as a factor in MPA designation and management (Appendix 2).

The relationship between seismic surveys and the diversity of species of cetaceans recorded in Brazil was evaluated in SC/57/E6. The information regarding diversity of cetaceans was obtained from Brazilian progress reports submitted to IWC from 1999 to 2003. Only presence/absence of species was scored due to broad variability of methods and sampling effort of various research groups. The data on seismic surveys between 1999 and 2003 were obtained from annual reports of the Brazilian Oil Agency (ANP).

A cluster analysis of the number of seismic surveys indicated a greater intensity of surveys in 2000 and 2001. Of the 43 species of cetaceans recorded in Brazil, 35 (85%) occurred during the study period. A cluster analysis of the presence/absence of species for each year, and the Shannon-Wiener diversity index showed a slight variation in the diversity of species among years, with some reduction in 2000 and 2001. The main decrease in observations was for common dolphins (*D. delphis*) and bottlenose dolphins. This investigation on the effects of seismic surveys on marine mammals in Brazil is very preliminary. It was recommended that data obtained during seismic surveys since 1999 be reviewed to further investigate diversity, abundance and distribution of cetaceans, with the goal of improving data sampling, monitoring and the focus of future research.

Some members raised concerns regarding lack of information on methodologies, which undermine comparison of stranding records before and after surveys. Further, if survey effort is concentrated in any one area, comparison against diversity monitoring nationwide may be problematic. Nevertheless, the results presented in this paper indicate some cause for concern and continued investigation is encouraged.

One member noted a study in which a significant decrease in minke whale sightings had been reported coincident with naval exercises (Parsons *et al.*, 2000). However, lack of provision of information on the position and activity of naval vessels and other data by the military made it impossible to assess possible confounding variables or study the effect in greater detail.

The SWG **strongly encourages** producers of high intensity noise (e.g. sonar and seismic operators) to share information on noise source characteristics and to work with cetacean scientists to investigate the impacts of these activities.

A workshop (entitled 'A workshop to identify potential impacts and mitigation strategies for offshore hydrocarbon industry activities with respect to marine mammals and other marine fauna in the Gulf of Guinea (central West Africa)') will be convened by the Wildlife Conservation Society (WCS) and the hydrocarbon industry to take place at the end of June 2005, where data and information about industry activity will be shared, and mitigation strategies will be discussed. One of the reasons this meeting is being convened is because of the extensive oil and gas development in West Africa, which potentially overlap with numerous critical habitats for endangered marine mammals. For example, the coastal waters of Gabon and other areas throughout the Gulf of Guinea are clearly one of the most important and best-documented wintering areas off equatorial West Africa for humpback whale breeding, calving and nursing, specifically from early July through October.

During the months of planning for the workshop, the initial terms of reference that have been established are:

(1) review relevant critical data and issues of key environmental concern particularly related to marine mammals;
(2) review relevant critical data and issues related to the state of industry activity in the Gulf of Guinea; and
(3) maximise conservation benefits for wildlife and critical habitat by identifying, based on the information identified in (1) and (2) above, areas of immediate opportunity for mitigations that are most easily implemented as operational mitigation measures.

It is expected that the attendees will be those directly involved in: (1) generating, interpreting, or utilising the science to characterise the regional ecosystem and potential impacts; and/or (2) industry operations in the region. This is envisaged as a first meeting to address these issues, share information, and attempt to identify areas of immediate opportunity for possible mitigations not currently or necessarily implemented.

Rosenbaum indicated that the report will be presented to the IWC SC 'Seismic Workshop' at SC/58. There are also a series of joint industry meetings focused on noise and on West Africa that will occur intersessionally. Following the proposed SC/58 Seismic Workshop, a second meeting with the regional hydrocarbon exploration and production (E&P) industry will be convened aimed at further discussion following a year of additional conservation research and monitoring in the region, as well as having the ability and purview to convey and discuss the recommendations on noise from the SC/58 Seismic Workshop to the regional hydrocarbon E&P industry.

The SWG welcomed this information and **strongly endorsed** the Workshop. The SWG looked forward to receiving the report of this workshop, especially with its relation to the work plan for SC/58.

Palazzo welcomed the summary of the industry and the partnerships between the conservation community and industry off the Atlantic coast of Africa. He encouraged collaboration with the conservation and management communities off the western part of the South Atlantic as well. Rosenbaum responded that, while he recognises that it is certainly an ocean basin-wide issue, he decided to focus originally on West Africa, where WCS has a strong conservation presence and is most likely to be able to effect change. It required tremendous co-operation between conservation and industry groups, and covering a larger area (including South America), might have watered down the efficacy of what they hoped to achieve.

SC/57/E16 reported that fishermen in different parts of the world have used sounds to herd various species of small cetaceans to mass strand or into harbours where they are killed and used for food. Some of these fisheries of acoustic hunting have existed for over 500 years. These fisheries are generally called 'drive fisheries' or 'the drive method'. Mitchell (1975) described

> 'in this type of fishery the animals are manoeuvred into a confining situation where they are either entrapped or immediately driven ashore and killed. Driving is usually accomplished with a number of small boats, which are used to herd the animals. In many cases, special efforts are made to generate noise, which aids both in containing the school and in hastening its movements'.

Fishermen around the world have independently used various types of low-intensity sounds to 'drive' schools of small cetaceans. The areas where we have the best information of 'drive fisheries' include Japan, Taiwan, Solomon Islands, Faroe Islands, and Newfoundland, Canada. Since the end of World War II, approximately 500,000 small cetaceans have been killed using the drive method and approximately 60% of these were killed in Japan.

SC/57/E16 also reviewed the use of ASDIC (name derived from the Anti-Submarine Detection Investigation Committee, also known as sonar) and sound for hunting large whales (baleen and sperm whales) in different parts of the world by commercial whaling operations. Tønnessen and Johnsen (1982) noted that the

> 'ASDIC produces bursts of sound that enable diving whales to be echo-located. It can be used in whaling in two different ways: (1) in the case of baleen whales, it frightens the animals, which then swim very fast and near the surface, making them easier to see and tiring them more quickly, (2) with sperm whales, its major use is in the tracking of lone animals while they are diving at great depths, enabling the catcher to be in the right place when they eventually surface'.

This pattern noted in baleen whales was precisely the reaction observed by Nowacek *et al.* (2004) when they played a synthetic alerting stimulus to North Atlantic right whales. Tens of thousands of large whales were killed faster and with greater efficiency with ASDIC.

Brownell also noted that mass strandings are often preceded by 'milling' events. SC/57/E16 recommended that the work by Touhey (2003) who reported using the combination of herding with small vessels and acoustic deterrents to prevent milling events from becoming stranding events be expanded to other regions where 'milling' events are known to occur. In addition, efforts are needed to document these efforts by a scientific team independently from the rescue team. The SWG agreed that this work is important, and **strongly recommended** that it be expanded.

One member asked whether there was anything about the properties of the ASDIC sounds (intensity, duration, frequency) that results in the observed responses. Others noted that information on ASDIC/sonar sources (including *inter alia*, frequency, source level and power spectra) is likely available, although it may be difficult to obtain, especially for sonars from the early years (i.e. 1940s and 1950s). The SWG urged that detailed information on acoustic sonars be obtained whenever possible because all sonars are not the same. This holds true also for seismic surveys. Detail on the type, number and configuration of airguns is needed to evaluate source capabilities.

The issue was raised as to whether other high-intensity sound sources (depth sounders, fish and krill detection equipment) might also affect whale behaviour in ways which may impact sighting surveys (e.g. altering surfacing behaviour, altering sighting cues or responsiveness to survey vessels). It was suggested that noting source level, frequency range and operation periods of such equipment used during sighting surveys may help to address such issues. Guidelines for use of such equipment might be necessary in particular if frequency ranges overlap those utilised by cetaceans.

SC/57/WW3 summarised several studies published over the last year related to whalewatching impacts, for which noise is a major component. The studies are covered in detail in the Whalewatching sub-committee report (Annex M), but some of the documented effects include increased swim speeds, habitat displacement and also reduced reproductive success.

Following last year's recommendations and the preceding discussion, a two day pre-meeting Workshop assessing the potential for seismic surveys to impact cetaceans was proposed for SC/58. The Workshop should review and characterise information on seismic sound sources, attenuation and their effects on cetaceans as well as review relevant case studies and current mitigation and monitoring strategies. A Steering Committee was formed and Rosenbaum was appointed as Convenor (see Appendix 3). The Committee **strongly endorses** the pre-meeting Workshop and agrees to the terms of reference.

9. OTHER ISSUES

SC/57/E7 described analysing blubber biopsy samples from adult male North Pacific killer whales for fatty acids, carbon and nitrogen stable isotopes and OC contaminants in order to learn more about the feeding ecology of these whales. Fatty acid and OC profiles were sufficiently distinct among the three reported ecotypes – the 'resident' (fisheaters), 'transient' (marine mammal eaters) and 'offshore' (unknown diet) ecotypes – to correctly classify the whales in this study by ecotype using previously developed discriminant function models. OC concentrations and ratios were used to provide additional insight on the dietary preferences of killer whales biopsied in Alaska, particularly for the offshores about which little dietary information is available. Surprisingly, mean ΣDDT and ΣPCB concentrations from the offshore ecotype approached or exceeded those of the transients. If the offshore ecotype were fish-eaters, concentrations of ΣPCBs and ΣDDTs should be more similar to those in the fish-eating residents, rather than to those of the marine mammal-eating transients. Thus, offshores must consume species containing high levels of ΣPCB and ΣDDT, or feed at a high trophic level, perhaps eating long-lived shark or tuna species. Furthermore, ratios of certain contaminants have been used to define regions from which prey may originate. Offshore contaminant ratios (e.g. ΣDDTs/ΣPCBs) generally fell between those of the West Coast transients and those of the Alaska residents and transients. Because the offshores are known to have a range that extends from Alaska to California, their contaminant ratios and other chemical profiles may represent those from a mix of prey species acquired from all areas in their range. To identify the particular species that comprise the diets of offshore killer whales, as well as those of the other ecotypes, chemical profiles must be measured in many more putative prey species collected from the killer whales' foraging areas.

It was indicated that this was an interesting paper and the question was asked as to whether OCs, stable isotopes and fatty acid data currently exist for sharks and tuna. The author indicated these data do not appear to be readily available so there is a need to target sampling from the specific area of feeding. It was also asked how many shark species were considered. The author replied that blue and thresher sharks off California are targeted and for Alaska it is less certain. It was indicated that we know of high mercury (Hg) levels in sharks and tuna so one should be curious about the concentrations of Hg in the offshore killer whales. The author also indicated that there are only small biopsy samples of epidermis, which are insufficient to analyse for metals. It is not known whether metals analysis of epidermal tissue will be predictive of levels in other tissues, especially based on the data from bowheads whales as described in SC/57/E11. It was asked if migration may have an effect on fatty acid profiles differently compared to, e.g. total PCB concentrations, since the rate of change in these indicators may be different. Thus, the area they occupy when sampled may not relate to the area reflected in the tissue sampled. The SWG indicated that this is an issue to consider. The Chair pointed out that mathematical models were a recommendation in the paper and was curious as to what the plan may be. It was replied that there are numerous analyses to consider and adding a modeller to look at the data is currently being considered.

SC/57/E11 investigated the ability of concentrations of elements in epidermal samples from bowhead whales to predict the corresponding elemental concentrations in blubber, kidney, liver and muscle. Epidermal concentrations had no predictive value for copper (Cu), manganese (Mn), lead (Pb), selenium (Se) or zinc (Zn) in any of the other tissues evaluated except that the epidermal measurement provided an upper bound for blubber concentration of Cu, Mn, Se and Zn. Epidermal concentrations of the four other elements considered were predictive for some other tissues. Arsenic (As) could be predicted in kidney, liver and muscle but not blubber, although the distribution of samples with concentrations below the minimum level reported (MLR, also known as the 'detection limit') and the resultant small sample sizes suggest that these data should be interpreted with caution. Epidermal concentrations of cadmium (Cd) were strongly predictive for blubber and weakly predictive for muscle concentrations. Epidermal concentrations of Hg were weakly predictive of blubber, liver and muscle concentrations. Epidermal concentrations of magnesium (Mg) were strongly predictive in blubber, kidney and liver, but only weakly predictive in muscle. Thus epidermal biopsy cannot predict concentrations in four key tissues in bowhead whales in most cases. Cobalt and molybdenum were not detected in any epidermal samples.

SC/57/E15 presented information on metal concentrations in cetacean tissues. Concentrations of six trace metals (As, Cd, Cu, Hg, Pb and Zn) were measured in the liver and the muscle tissues of bycaught common minke whales (*B. acutorostrata*) in Korean waters. The metal concentrations were detected in the sequence of Zn>Cu>As>Hg>Pb>Cd in the liver tissues and Zn>Cu>As>Pb>Cd>Hg in the muscle tissues. The concentrations in the liver tissues were higher than in the muscle tissues by about an order of magnitude, except for Pb. The concentrations of Cd and Hg in the tissues of males were significantly higher than in females and of animals from the East Sea higher than the Yellow Sea in the liver tissues. No significant differences were observed among size classes.

The SWG thanked Kim for bringing the data. It was noted that these data could be compared with contaminant levels in minke whale meat from the same area obtained from market sampling. The authors indicated that no such comparisons have yet been made.

10. WORK PLAN AND PRIORITIES FOR 2005/2006

10.1 SOCER

The Commission (Resolution 2000/7) has encouraged continuation of SOCER. The budget presented for the 2006 SOCER is in Appendix 4. The requested funding would support the editors' time spent searching the literature, editing, and compiling entries, and communicating and co-ordinating with the SC and the wider scientific community. It will also reimburse the material costs of monitoring, searching and procuring publications and producing the document. Also, as requested by the SC Chair, a new feature of SOCER will involve a search of abstracts to compile statistics on publications related to cetacean ecology, life history and other biological and management issues published in the preceding calendar year.

10.2 Sea ice

High priority intersessional projects identified jointly by the E, IA and BRG sub-committee during the Sea Ice Symposium (SC/57/Rep5) are targeted at issues in polar regions (budget provided in Appendix 4). The Arctic sea ice WG proposed two studies for intersessional work. The first is focused on retrospective analyses of sea ice conditions, using both satellite-derived data and traditional ecological knowledge (TEK) to collate with extant records of BCB bowhead and ENP gray whale population dynamics. The second project then seeks to investigate health status in both populations with regard to variability in sea ice. The SWG **recommends** that these studies be supported.

A core set of six analysis projects were developed from the initial focus questions for the Antarctic group. Analysis projects were considered on the basis of the availability of appropriate whale and environmental data series at appropriate scales, relevance to the work of IA and E sub-committees, potential to contribute towards resolving high priority issues in the SC, and the interest and willingness of invited experts and symposium participants to source data series and conduct the work intersessionally. Antarctic projects include: (1) areas of high minke density; (2) shelf break position correlation with whale distribution; (3) data-rich regional comparisons of variables affecting distribution; (4) analysis of minke whale distribution and relative proportions inside and outside the pack ice; (5) integration of historical and recent whale catch/sighting data; and (6) support for the completion of the SOC Database. A request for funding to continue core work of the environmental concerns SWG conducted under the IWC SOC WG for IWC collaboration on the two final SO-GLOBEC cruises and support for Thiele for co-ordination, analysis and development of IWC as a core component of ICCED was requested. The SWG **recommends** that these studies be supported.

10.3 2006-Seismic Workshop

Following on identified priorities for upcoming workshops (IWC, 2005b), a two-day pre-meeting workshop to assess the potential for seismic surveys to impact cetaceans was proposed as part of the SWG on environmental concerns at SC/58 (Appendix 3). The proposed meeting was **strongly endorsed** by the SWG. The SC is in a position to synthesise and evaluate the relevant information on this issue and provide the appropriate recommendations. A Steering Committee was formed (Moore, Simmonds, Rosenbaum, Rowles, Findlay, Rojas, and Williams) and Rosenbaum was appointed Chair. The rationale, initial terms of reference, draft agenda, and suggested Invited Participants are provided in Appendix 3. The terms and agenda for the Workshop will be finalised intersessionally by the Steering Committee. In discussion of this topic, it was noted that other sub-committees (e.g. BRG, BC and SM) could be interested in the multidisciplinary nature of this topic.

It was recommended that participants with the most appropriate technical and regional expertise be invited and that sufficient funds be made available to facilitate their attendance. The SWG also agreed that representation from developing countries and the success of future Workshops is directly related to the expertise of appropriate Invited Participants. The SWG **endorsed** the Workshop.

The budget requested for the Seismic Workshop is in Appendix 4.

10.4 2007-Diseases

At SC/56, the SWG proposed diseases as a focus of the 2007 meeting. It was noted that ICES is developing plans for a workshop on diseases of marine animals. A recent participant in these discussions of the proposed ICES workshop indicated that a member or members of IWC SC should attend. The topic of diseases includes both infectious and non-infectious issues. The SWG requires a more focussed approach, and the emerging issue of biotoxins produced by harmful algal blooms (HABs) was suggested. Harmful algal blooms have been documented as the cause of numerous mass mortalities in marine mammal populations and have been increasing in frequency and expanding to global geographic distribution. In some cases, human activities potentiate bloom occurrence and magnitude through nutrient loading of coastal waters, the inadvertent transport of harmful species to novel places, and ecosystem effects of overfishing. There are many physical, chemical and biological features that may increase exposure and vulnerability to biotoxins, and certain species or cohorts of cetaceans may be uniquely sensitive to the harmful effects (include lethal). For these reasons, the SWG **endorsed** the plan to review available information on HABs and cetaceans in 2007 and **agreed** that participation in the ICES disease workshop would be beneficial.

10.5 2008-Suggestions

Two topic areas for discussion in 2008 were proposed. Emerging pollutants such as PBDEs were proposed as a focus area for the 2008 meeting, noting that they were last reviewed in 2001 (Simmonds *et al.*, 2001). Three years would give researchers enough time to collect data and do the science required to present reports if requested. Reijnders pointed out that the recommendation in the Habitat Degradation Workshop Report on further execution of the framework presented (Fig. 1), could be promoted by having habitat degradation as a focus area for the 2008 meeting. Meanwhile, the modelling required in the framework using case studies may have progressed enough to have produced relevant results by that time. The SWG requested information on both of these areas for consideration at the 2006 meeting, at which time it could make a decision about a priority topic in 2008. The SWG accepted this suggestion.

11. ADOPTION OF REPORT

The report was adopted at 17:30 on 6 June 2005.

STATE OF THE CETACEAN ENVIRONMENT REPORT (SOCER) 2005

Editors: M. Stachowitsch[1], E.C.M. Parsons[2] and N.A. Rose[3]

Introduction

The first edition of the State of the Cetacean Environment Report (SOCER) was submitted to the International Whaling Commission Scientific Committee (SC) in 2000 in response to several resolutions from the Commission, including Resolutions 1997-7 and 1998-5, which directed the SC to provide regular updates on environmental matters that affect cetaceans. Resolution 2000-7 welcomed the submission of the first SOCER at the 52nd Annual Meeting in Adelaide, Australia, and 'request[ed] the annual submission of this report to the Commission'. Previous SOCERs have focused on the Atlantic Ocean, the Mediterranean Sea, and the Pacific Ocean. SOCER 2005 (presented to the meeting as SC/57/E8) focuses on the Arctic and Southern Ocean (polar) regions, summarising key papers and articles that have been published in 2003, 2004, and to date in 2005.

ARCTIC

Habitat protection/degradation

Arctic ozone decimated by solar storms

Satellite data showed that a record discharge of charged particles from the sun in October and November 2003 destroyed large amounts of ozone. Electrons from the sun ionised nitrogen, which in turn formed nitrogen oxides with Chlorofluorocarbon (CFC)-like effects, destroying an estimated 60% of the ozone above the Arctic during spring 2004. Ozone levels remained low until July 2004.

Chemical pollution

Radioactive contamination of the Arctic Ocean

One of the latest Arctic Ocean surveys by the Swedish Polar Secretariat examined the concentrations of iodine-129 from the Norwegian coast to the North Pole. This radioactive component of nuclear fuel waste is released from nuclear processing facilities at La Hague, France, and Sellafield, UK. The study reveals a two-fold increase in the upper 1,000m since 1996 and predicts another doubling in the Arctic Ocean between 2001 and 2006. This demonstrates that radioactive contaminants, as with other pollutants produced in temperate zones, make their way to and become concentrated in ecologically sensitive waters of polar regions.

(SOURCE: Alfimov V., Aldahan A., Possnert G., and Winsor P. 2004. Anthropogenic iodine-129 in seawater along a transect from the Norwegian coastal current to the North Pole. *Mar. Poll. Bull*. 49: 1097-1104)

Factors influencing bioaccumulation of persistent organic pollutants in Arctic food webs

The Arctic ecosystem has a number of unique attributes, including long food chains, reduced diversity of species, similar food webs across the entire region, and limited influence from pollution point sources. Organochlorine (OC) concentrations and bioaccumulation in Arctic marine biota are influenced by lipid content, body size, age, gender, reproduction, habitat use, migration, biotransformation, seasonal changes in habitat conditions, feeding ecology and trophic position. Diet or trophic level is the dominant factor influencing OC concentrations and dynamics in seabirds and marine mammals, although biotransformation can significantly influence contaminants such as hexachlorocyclohexane isomers. Although models developed to assess OC dynamics in aquatic food webs have included biological variables (e.g. lipid content, feeding rate, diet composition, growth rate), these models are all highly simplified. This reduces the biological validity of the models and may be particularly problematic in a highly seasonal environment, such as the Arctic.

(SOURCE: Borga, K., Fisk, A.T., Hoekstra, P.F., and Muir, D.C.G. 2004. Biological and chemical factors of importance in the bioaccumulation and trophic transfer of persistent organochlorine contaminants in arctic marine food webs. *Environ. Toxicol. Chem.* 23(10):2367-85)

Levels of contaminants in Arctic cetaceans

The organochlorine levels in 75 harbour porpoises from Greenland were generally found to be low. However, some harbour porpoises in northern Norway, some resident killer whales and all transient killer whales in Alaska, and some long-finned pilot whales in the Faeroes display levels of Polychlorinated biphenyls (PCBs) that have induced immunosuppression and reproductive failure in other mammalian species. Reproduction in fish-eating marine mammals such as minke whales, white whales, narwhals, long-finned pilot whales and harbour porpoises may be affected as the result of consuming PCB-contaminated fish. Killer whales consuming contaminated marine mammals may exhibit PCB-related reproductive abnormalities. Contaminant levels (especially PCBs, DDT and dioxin-like substances) in cetacean prey species (fish and molluscs) should be considered and monitored when managing and issuing guidelines to protect marine species.

MAXIMUM CONTAMINANT LEVELS

Mature male harbour porpoises from Nuuk, Greenland (ng g^{-1} lipid weight) HCB: 300; ΣDDT: 5780; ΣPCB: 3750.

Pollut.* 128: 381-391; De Wit, C., Fish, A., Hobbs, K., Muir, O., Gabrielsen, G., Kallenborn, R., Krahn, M.M., Norstrom, R. and Skaare, J. 2004. *AMAP Assessment 2002: Persistent Organic Pollutants in the Arctic.* Arctic Monitoring and Assessment Program, Oslo, Norway)

Contamination trends in West Greenland narwhals

A total of 150 narwhals harvested in subsistence hunts were analysed for OC and heavy metal contamination. Cadmium, selenium and mercury levels increased in animals during the first 3-4 years of life, after which no trend was observed. Females tended to have higher heavy metal contaminant

[3] Humane Society International, Washington, DC, USA.

loads than males. Females showed decreases in OC levels for their first eight to ten years of life, but levels increased after ten years of age. Male OC levels increased in the first few years; levels tended to be stable after that. Levels of organochlorines in western Greenland were considered to be similar to animals in the Canadian Arctic, but were half of the levels recorded in East Greenland and Svalbard.

MAXIMUM CONTAMINANT LEVELS

Mean narwhal liver values (ng g^{-1} wet weight) Cd: 39900; Hg: 16300; Se: 12000; Zn: 40000

Mean narwhal (7yr old males) blubber values (ng.g^{-1} lipid weight) HCB: 1001; ΣHCH: 219; ΣCBH: 2376; ΣDDT: 4964; ΣPCB: 2160; ΣTOX: 5955.

Recent increases in air-borne heavy metal pollution

A study on atmosphere-borne trace element contaminants in the Arctic troposphere determined that anthropogenic heavy metals such as lead, zinc and copper, as well as sea salt-associated sodium and magnesium, were highest in the winter and lowest in the summer. Elements carried in soil dust (aluminium, barium, calcium, iron and manganese) peak briefly in spring (April-May; due to long-range atmospheric transport of dust from Eurasian deserts) and in the autumn (September-October; due to locally windblown dust and soil). There were no long-term trends in sodium, manganese and calcium concentrations, but levels of soil-associated aluminium, iron and titanium have tended to decrease after 1995. Although there was a decrease in atmospheric lead, zinc, nickel and copper in the 1980s, this stabilised and levels started to increase after 1995. In a comparison of atmospheric contamination in Arctic regions, trace element levels in the eastern Russian Arctic were on average three to four times higher than levels recorded in Barrow, Alaska, and Alert, Canada, supporting a Eurasian source of atmospheric trace element pollution in the Arctic.

(SOURCE: Gong, S.L. and Barrie, L.A. 2005. Trends of heavy metal components in the Arctic aerosols and their relationship to the emissions in the Northern Hemisphere. *Sci. Total. Environ.* 342: 175-183)

Research into link between atmosphere and aquatic environment required

Most persistent organic pollutants (POPs) are transported to the Arctic by the atmosphere. The transport mechanisms involved are complicated, with trends and patterns in the Canadian Arctic probably differing from those in the European/eastern Arctic. The role of snow and ice – and the transfer of contaminants via river-ice to sea-ice and subsequent transport across the Arctic – distinguish the processes here from those in temperate regions. The roles of snow, ice and wind conditions in the fate of contaminants are still poorly understood and research is needed to shed light on the link between the atmosphere (the source) and the aquatic environment.

(SOURCE: Halsall, C.J. 2004. Investigating the occurrence of persistent organic pollutants (POPs) in the Arctic: their atmospheric behaviour and interaction with the seasonal snow pack. *Environ. Pollut.* 128: 163-175)

First record of polychlorinated naphthalenes (PCNs) in marine mammals in the Canadian Arctic

Polychlorinated naphthalenes (PCNs) are a group of 75 compounds manufactured as complex technical mixtures with past industrial applications. Samples of white whale blubber collected from subsistence hunts from Baffin Island, Canada, were analysed for polychlorinated naphthalenes (PCNs). Levels of toxic coplanar PCBs were also determined. Although concentrations of PCNs were less than 1% of the coplanar PCBs, they contributed to 11% of the toxicity (TEQ) of the sample. This is the first study to record this toxic class of anthropogenic compound in Arctic marine mammals.

MAXIMUM CONTAMINANT LEVELS

ΣPCN (pg.g^{-1} lipid weight): 383; ΣCoplPCB (ng g^{-1} lipid weight): 317.

(SOURCE: Helm, P.A., Bidleman, T.F., Stern, G.A. and Koczanski, K. 2002. Polychlorinated naphthalenes and coplanar biphenyls in white whales (*Delphinapterus leucas*) and ringed seal (*Phoca hispida*) from the eastern Canadian Arctic. *Environ. Pollut.* 119: 69-78)

High levels of polychlorinated naphthalenes in the Norwegian Arctic

The deposition and accumulation of POPs in the Arctic snow pack are important steps in their transfer from the atmosphere to the marine environment. The levels of PCNs in the Norwegian Arctic greatly exceeded those in the Canadian Arctic and were within the upper ranges of the eastern Arctic Ocean. Snow densities had a considerable effect in explaining variation in the concentrations, with denser, aged snow having lower values. The high levels of PCNs, coupled with their dioxin-like toxicity, warrant further investigation into the fate of these chemicals in the Arctic.

(SOURCE: Herbert, B.M.J., Halsall, C.J., Villa, S., Fitzpatrick, L., Jones, K.C., Lee, R.G.M. and Kallenborn, R. 2005. Polychlorinated naphthalenes in air and snow in the Norwegian Arctic: a local source or an Eastern Arctic phenomenon? *Sci. Total Environ.* 342:145-160)

Pollutants potentially differentiate Arctic minke whale stocks

The levels of persistent OCs in the blubber of 155 minke whales from seven management regions (IWC *Small Areas*) in the European Arctic revealed a general increase from west to east. Minke whales from the Barents Sea, for example, had significantly higher levels of OCs than those from several other regions, including the North Sea. The distinction of the western Greenland minkes from other IWC-defined stocks in northern European waters agrees with findings from genetic and other studies. On the other hand, the general similarity in mean levels of PCBs, DDT and others suggest that the whales are quite mobile and may feed in multiple areas. The distinct differences in certain OC compounds illustrate the potential of pollutant levels in helping to distinguish whale stocks.

MAXIMUM CONTAMINANT LEVELS

Arctic minke whale (ng g^{-1} lipid weight) HCB: 544; ΣCHL: 2110; ΣDDT: 6280; ΣHCH: 497; ΣPCB: 22800

Relatively low levels of organochlorines in Alaskan bowhead whales, higher levels in white whales

Bowhead whale tissues and uncooked maktak (skin and blubber) were collected during subsistence hunts at Barrow, Alaska from 1997 to 1999. Concentrations of OCs in these tissues were low compared to other marine mammals, due to the lower trophic status of this species. There were no statistical differences in contaminant levels between most

tissues, although HCH was higher in heart and diaphragm tissues. OC levels were also analysed in samples from bowhead and white whales collected during subsistence hunts in 1999 and 2000. Levels of contamination in white whales were greater than in bowhead whales, which was attributed to white whales occupying a higher trophic level. When compared to contaminant levels in prey species, contaminant levels in white whales blubber were greater by a factor of up to 46.5 times (this maximum was for DDE – for PCBs, the factor was 24.4; for DDT, 23.0; for chlordane, 13.5; for chlorobenzene, 4.3; and for HCH, 3.7).

MAXIMUM CONTAMINANT LEVELS

Blubber (ng g^{-1} wet weight) HCB: 273; ΣCHL: 701; ΣDDT: 1925; ΣHCH: 763; ΣPCB: 1305.

MEAN CONTAMINANT LEVELS

White whale (ng g^{-1} lipid weight) ΣClBz: 330; ΣHCH: 224; ΣCHL: 1320; ΣDDT: 1979; ΣPCB: 3305.

Bowhead whale (ng g^{-1} lipid weight) ΣClBz: 196; ΣHCH: 282; ΣCHL: 1260; ΣDDT: 437; ΣPCB: 541.

(SOURCE: Hoekstra, P.F., O'Hara, T.M., Backus, S.M., Hanns C. and Muir, D.C.G. 2005. Concentrations of persistent organochlorine contaminants in bowhead whale tissues and other biota from northern Alaska: implications for human exposure from a subsistence diet. *Environ. Res*. 98(3):329-340; Hoekstra, P.F., O'Hara, T.M., Fisk, A.T., Borgå, K., Solomon, K.R. and Muir D.C.G. 2003. Trophic transfer of persistent organochlorine contaminants (OCs) within an Arctic marine food web from the southern Beaufort-Chukchi Seas near Barrow, Alaska. *Environ. Pollut.* 124: 497-507)

Organochlorines concentrated along an Arctic marine food web

The biomagnification of persistent OCs along the Arctic marine food web is promoted by the efficient transfer of lipids and the nutritional demands of higher level mammalian predators. The concentration of certain OCs increased along a food web in the Southern Beaufort-Chukchi Seas and was significantly higher in cetaceans, such as bowhead and white whales, than in fish. The values were consistent with those reported from the Canadian Arctic and temperate food webs, but not with those from the Barents and White Seas. This suggests that the variability is due to differences in contaminant exposure, underlining the importance of examining pollution exposure and risks on a regional basis.

(SOURCE: Hoekstra, P.F., O'Hara, T.M., Fisk, A.T., Borga, K., Solomon, K.R. and Muir, D.C.G. 2003. Trophic transfer of persistent organochlorine contaminants (OCs) within an Arctic marine food web from the southern Beaufort-Chukchi Seas. *Environ. Pollut.* 124: 509-522)

Global atmospheric patterns necessary to explain transport of pollutants to Arctic

Several classes of POPs were examined in the air at Canadian and Russian Arctic sites between 1992 and 2001. One site showed a decline of OCs and particulate polycyclic aromatic hydrocarbons (PAHs); the latter was attributed to the collapse of industrial activity in the former Soviet Union between 1991 and 1995. A seasonality of concentrations, with recurring elevated levels in spring, was recorded. The air concentrations were influenced by two climate variation patterns, the North Atlantic Oscillation (NAO) and the Pacific North American (PNA) pattern. In the future, planetary atmospheric patterns must be taken into account in the global prediction and modelling of POPs.

(SOURCE: Hung, H., Blanchard, P., Halsall, C.J., Bidleman, T.F., Stern, G.A., Fellin, P., Muir, D.C.G., Barrie, L.A., Jantunen, L.M., Helm, P.A. and Konoplev, A. 2005. Temporal and spatial variabilities of atmospheric polychlorinated biphenyls (PCBs), organochlorine (OC) pesticides and polycyclic aromatic hydrocarbons (PAHs) in the Canadian Arctic: Results from a decade of monitoring. *Sci. Total Environ.* 342(1-3):119-144)

Exponential increase of flame retardants in Canadian white whales

The levels of polybrominated diphenyl ethers (PBDEs), used in flame retardants, showed a significant exponential increase between 1988 and 1999 in white whales from the St. Lawrence Estuary in Canada. Although the levels are still below those reported for other marine mammals, these white whales doubled their blubber concentration every three years. These are among the fastest rates of increase measured in wildlife. This accumulation was recorded in both males and females, and ongoing strong uptake apparently masks the elimination by females via milk to suckling calves. In a population that has declined to 1,000 individuals, i.e. by about 80-90% of its estimated size in 1885, these developments warrant continued close monitoring.

(SOURCE: Lebeuf, M., Goutex, B., Measures, L. and Trottier, S. 2004. Levels and temporal trends (1988-1999) of polybromilated diphenyl ethers in white whales (*Delphinapterus leucas*) from the St. Lawrence Estuary, Canada. *Environ. Sci. Technol.* 38: 2971-2977)

Persistent organochlorine pesticides in the Arctic

The Arctic has become a sink for various anthropogenic compounds such as persistent OCs, largely after long-range transport from temperate environments. Using HCH as an example, this study reveals that the pathways of different forms of HCH to the Arctic differ; for example, α-HCH is transported via the atmosphere and β-HCH via ocean currents. While α-HCH concentrations in white whales from Cumberland Sound are decreasing, β-HCH concentrations are increasing. Bowhead whales exhibit a reversal in their blubber α/β-HCH ratios as they migrate and feed annually between the Bering and the Beaufort Sea. These differences underline the complexity of chemical pollution in the Arctic and the need for detailed research to provide adequate databases.

(SOURCE: Li, Y.F. and MacDonald, R.W. 2005. Sources and pathways of selected organochlorine pesticides to the Arctic and the effect of pathway divergence on HCH trends in biota: a review. *Sci. Total Environ.* 342: 87-106)

Modelling the transport of PCBs to the Arctic

This study selected four of the more than 200 different forms of PCBs for a modelling approach. Contamination of the Arctic takes place from two sources, northwest Europe and America (30% and 19%, respectively), but at different seasons. American sources penetrate the Arctic in May, European sources in January, in line with the annual atmospheric circulation patterns in the Arctic. Interestingly, the model considers sea ice coverage: melting snow and ice passes contaminants into the aquatic environment. Thus, warmer temperatures associated with climate change could accelerate the input of PCBs into Arctic marine food chains.

(SOURCE: Malanichev, A., Mantseva, E., Shatalov, V., Strukov, B. and Vulykh, N. 2004. Numerical evaluation of the PCBs transport over the Northern Hemisphere. *Environ. Pollut.* 128: 279-289)

New class of persistent contaminants in the Arctic food chain

A new class of persistent fluorinated contaminants, in particular perfluoroctane sulfonate (PFOS), has been detected for the first time in a wide range of animals in the Canadian Arctic, from fish and common loons to polar bears and ringed seals. PFOS levels were more substantial in polar bears than PCB levels. Mammals feeding at higher trophic

levels had higher concentrations. Future studies should examine the toxicities of this novel group of compounds. Their detection in seals suggests that Arctic cetaceans also have these contaminants in their tissues.

MAXIMUM CONTAMINANT LEVELS

PFOS (ng g^{-1}) polar bears >4000; ringed seals 37.

(SOURCE: Martin, J.W., Southwick, M.M., Braune, B.M., Hoekstra, P.F., Muir, D.C.G. and Mabury, S.A. 2004. Identification of long-chain perfluorinated acids in biota from the Canadian Arctic. *Environ. Sci. Technol.* 38: 373-380)

Review of pollutant trends in Greenland

A study that reviewed and compared organic and inorganic contaminant data from Greenland determined that mercury levels tended to be greater in marine biota from east Greenland, whilst cadmium levels were greatest in western Greenland. Although there were not enough data to analyse long-term temporal trends in cetaceans, generally ringed seals have increasing levels of mercury, but decreasing levels of cadmium, contamination since the 1980s. Typically, marine species also had greater PCB, DDT and HCH concentrations in eastern, compared to western, Greenland. PCB levels in polar bears in east Greenland have decreased substantially in the last decade, as have HCH levels in seals generally, but DDT levels in seals have increased in western Greenland. Similar trends may be likely in other marine mammals such as cetaceans.

(SOURCE: Riget, F., Dietz, R., Vorkamp, K., Johansen, P. and Muir, D. 2004. Levels of spatial and temporal trends of contaminants in Greenland biota: an updated review. *Sci. Total Environ.* 331: 29-52)

Naturally occurring organohalogens in bowhead and white whales

Four halogenated dimethyl bipyrroles (HDBPs), which are possibly naturally occurring, were evaluated in marine mammal blubber from a variety of species, including Arctic white and bowhead whales. Levels of pollutants in Alaskan white whales were higher than in animals from Canada, which in turn were higher than concentrations in Svalbard. Higher levels were deemed to be the result of being closer to a North Pacific source of these contaminants. Levels in bowhead whales in the Beaufort Sea were considerably lower.

MAXIMUM CONTAMINANT LEVELS

ΣHDBP (ng g^{-1} lipid weight) white whale, Alaska: 99.2; Canada: 54.4; Svalbard: 6.1; bowhead whale: 1.8.

(SOURCE: Tittlemier, S., Borrell, A., Duffe, J., Duignan, P.J., Fair, P., Hall, A., Hoekstra, P., Kovacs, K.M., Krahn, M.M., Lebeuf, M., Lydersen, C., Muir, D., O'Hara, T., Olsson, M., Pranschke, J., Ross, P., Siebert, U., Stern, G., Tanabe, S. and Norstrom, R. 2002. Global distribution of halogenated dimethyl bipyrroles in marine mammal blubber. *Arch. Environ. Contam. Toxicol.* 43: 244-255)

Long chain perfluorinated acids found in white whales and narwhals

Samples of white whale and narwhal liver from animals harvested in subsistence hunts in Nunavut, Canada, were analysed for polyfluorinated contaminants: all fluorinated compounds investigated were found in these cetacean tissues. Samples of other biota from different trophic levels were also analysed; it was determined that PFOS biomagnifies, with approximately a threefold increase in contamination with increasing trophic level. This, therefore, adds another anthropogenic contaminant of concern that should be evaluated in Arctic cetaceans.

MAXIMUM CONTAMINANT LEVELS

White whale (ng g^{-1} wet weight) PFOS: 15.8; PFOA: 2.8; N-EtPFOSA: 11.7; PFOSA: 48.4.

Narwhal (ng g^{-1} wet weight) PFOS: 17.7; PFOA: 1.1; N-EtPFOSA: 6.9; PFOSA: 10.9.

(SOURCE: Tomy, G.T., Budakowski, W., Halldorson, T., Helm, P.A., Stern, G.A., Friesen, K., Pepper, K., Tittlemier, S.A. and Fisk, A.T. 2004. Fluorinated organic compounds in an eastern Arctic marine food web. *Environ. Sci. Technol.* 38: 6475-6481)

Europe and Asia greatest contributors to Arctic HCH contamination

Researchers modelling the transport of α–HCH from temperate regions where the contaminant was produced to the Arctic determined that Europe and greater Asia (including China and southeast Asia) had the greatest impact on α–HCH in the Arctic, with high levels of emission of this contaminant in Asia and moderate levels of emission in Europe, but greater transferability of the contaminant in the latter region into the Arctic.

(SOURCE: Toose, L., Woodfine, D.G., MacLeod, M., Mackay, D. and Gouin, J. 2004. BETR-World: a geographically explicit model of chemical fate: application to transport of α–HCH to the Arctic. *Environ. Pollut.* 128: 223-240)

Immunotoxic and hormone-disrupting PBDEs in Arctic cetaceans

Although levels were deemed to be relatively low, a study on polybrominated diphenylether (PBDE) contamination (primarily from brominated fire retardants) in Arctic marine mammals from Svalbard noted that white whales do display contamination by this chemical group despite being in a 'pristine' environment. Levels of these contaminants were higher than levels recorded in the Canadian Arctic (nine times higher in the case of contaminated juveniles). White whales had higher contaminant loads than ringed seals feeding on similar prey, possibly due to an inability to metabolise these compounds. As PBDEs were seen to bioaccumulate in a similar fashion to PCBs and are known to have immunotoxic and endocrine-disrupting effects, and as they continue to be produced and used in increasing amounts, they will no doubt pose an increasing environmental threat for the Arctic and its wildlife.

MAXIMUM CONTAMINANT LEVELS

ΣPBDE (ng g^{-1} lipid weight) white whale calf: 279; juvenile white whale: 314.

(SOURCE: Wolkers, H., Van Bavel, B., Derocher, A.E., Wiig, Ø., Kovacs, K.M., Lydersen, C. and Lindström, G. 2004. Congener-specific accumulation and food chain transfer of polybrominated diphenyl ethers in two Arctic food chains. *Environ. Sci. Technol.* 38: 1667-1674)

Disease and mortality events

Immune system of Arctic cetaceans impaired by PCBs

This study supports the theory that OCs, particularly PCBs, are increasingly a cofactor in the deaths of marine mammals. Examinations of the blood of white whales (and bottlenose dolphins) revealed that non-coplanar PCBs suppressed the immune response of cells, i.e. their ability to digest extracellular molecules in a process known as phagocytosis. The results imply that wild populations of these cetaceans may be at risk of succumbing to normally non-threatening diseases because their immune systems may be compromised due to environmental contaminant exposure.

Climate change

Arctic warming heralds global impacts

The Arctic is now experiencing some of the most rapid and severe climate change on earth. Over the next 100 years, climate change is expected to accelerate, contributing to many physical and ecological changes, some of which have already begun. Sea ice reduction, sea level rise, increased storms, and (at least temporarily) more productive marine fisheries may result in unpredictable changes in marine fauna distribution and population trends. The exact impact these significant and wide-ranging environmental changes will have on Arctic cetacean populations is unknown and may be less than for terrestrial and ice-dependent species, but food webs involving cetaceans will almost certainly be disrupted in various ways.

(SOURCE: ACIA. 2004. *Impacts of a Warming Arctic: Arctic Climate Impact Assessment*. Cambridge University Press, *http://www.acia.uaf.edu*)

High levels of warming and ice melting in the Arctic

According to satellite data, a high rate of warming has occurred over the Arctic region in the last two decades. Temperatures have increased 0.54°C per decade over sea ice, 0.85°C over Greenland and 0.79°C over North America, but there has been only a 0.14°C decrease in temperature over Eurasia. Previous data based on satellite imagery underestimated the degree of warming by half. Due to changes in stratospheric temperature, ozone levels in the Arctic are also decreasing by approximately 1% per year. In addition, the region of melting ice on the Greenland ice sheet has increased by 17% between 1992 and 2002. Snow cover has also decreased in the Northern Hemisphere, at a rate of 2.6% per decade, and 15% of the Arctic tundra has been lost since the 1970s (an area three times the size of California). As 14% of the world's carbon is stored in the Arctic, reductions in permafrost, and the resulting release of stored greenhouse gases such as carbon dioxide and methane, are a cause for concern. With respect to cetaceans, the high rates of sea ice loss are particularly relevant – a 9.2% decrease in perennial sea ice per decade. It is also suggested that the upper water layers of the Arctic Ocean are 10% less saline than in the 1970s, the result of ice melting and increased river flows.

Scientists to use submarine to investigate Greenland ice sheet

To investigate the underside of Greenland ice sheets and advance research on patterns of ice sheet melting and contributions to sea level rise, scientists are planning to use an automated submarine. This novel technique will hopefully address and clarify some of the issues involved in sea ice melting in the Arctic.

(SOURCE: Haag, A. 2004. Greenland ice sheet to get an underhand inspection. *Nature* 430: 955)

Greenland glacier rapidly increasing discharge

Scientists monitoring the flow of the Jakobshavn Isbræ glacier noticed an increase in flow from 5,700m yr^{-1} in 1992, to 9,400m yr^{-1} in 2000, to 12,600m yr^{-1} in 2003. Since 1997 the glacier has been thinning at a rate up to 15m yr^{-1}. This increased flow of glacier ice, and hence additional water, into the coastal waters of Greenland has implications for oceanographic conditions and may hasten sea level rises. The researchers note that the flow of the Jakobshavn Isbræ glacier has contributed to about 4% of the 20th century sea level rise, so its increased flow could have significant effects. The researchers also note the rapidity with which flow rate has increased.

(SOURCE: Joughin, I., Abdalati, W. and Fahnestock, M. 2004. Large fluctuations in speed on Greenland's Jakobshavn Isbræ glacier. *Science* 432: 608-610)

Arctic sea ice trends may impact narwhal

An analysis of narwhal habitat use in conjunction with data on sea ice trends was conducted to investigate possible impacts of global warming on narwhals. In particular the limited number of leads and cracks in ice in winter, in conjunction with localized decreasing trends in open water and high site fidelity, suggest that narwhals are very vulnerable to sea ice changes, including greater risks of sea ice entrapments. Researchers note that '[e]stimates of sustainable levels of exploitation should also include the risks of sudden large-scale mortalities on the wintering grounds'.

The Bering Sea is getting warmer

Starting in 1996, spring has consistently come earlier in the Bering Sea, and since 1976 there have been warmer summers. Air temperature records from St. Paul Island also indicate air temperatures were warmer in the region in the last two decades, and the 20th century was warmer than the 19th century. The mean number of days during which there was more than 5% ice cover in the Bering Sea after 1 January has decreased from 130 days (1971 to 1976) to 67 days (1977 to 1989). The presence of sea ice is related to phytoplankton growth – when there is ice present after mid-March, phytoplankton blooms earlier (due to ice-phytoplankton associations); when no ice is present, phytoplankton blooms in May or June. A late bloom means more prey is available to pelagic species, but an early bloom favours benthic species as dying plankton falls to the seabed. This would be expected to cause a shift in the Bering Sea ecosystem and it was suggested that recent increases in pelagic walleye pollock and decreases in bottom-living Pacific cod are linked to these phytoplankton, and hence climatic changes. The data suggest that there is a climate-influenced shift and alteration in the Bering Sea ecosystem that could ultimately affect Arctic cetaceans.

(SOURCE: Overland, J.E. and Stabeno, P.J. 2004. Is the climate of the Bering Sea warming and affecting the ecosystem? *Eos* 85(33): 309-316)

Retreating glaciers in Alaska may cause increase in earthquakes

Researchers discovered decreases in average ice thickness of 1-5m *per annum* in south central Alaska between 1995 and 2000. The losses of ice resulted in movements of underlying land and horizontal deformation of up to 4cm *per annum*, in response to the loss of the overlying weight. The land deformation was such that changes in positions of specific sites could be measured using a global positioning system (GPS). During the 20th century, this region has experienced losses in ice thickness of up to 1km. It was also suggested that increasing seismic activity in the region is linked to the thinning ice cover. Both a decrease in ice and the potential for increased seismic activity may affect cetacean habitats, and in the case of earthquakes may cause increased exposure to tsunamis and to high source levels of noise.

(SOURCE: Sauber, J.M. and Molina, B.F. 2004. Glacier ice fluctuations and fault instability in tectonically active southern Alaska. *Global Planet Change* 42: 279-293)

Global warming may cause Arctic ozone hole
Scientists argue that climatic changes resulting from global warming led to an unusually cold Arctic winter in 2004. Also greenhouse gases are believed to lead to colder temperatures in the stratosphere as more heat is locked near the surface, and less escapes to warm the upper atmosphere. This cold temperature is believed to have led to increases in cold temperature clouds (which form at temperatures <-80°C), upon whose surface CFC compounds can adhere, destroying ozone molecules. In some areas of the Arctic more than half of the atmospheric ozone molecules have been destroyed. Ozone loss in the Arctic is less severe than in the colder Antarctic, but researchers predict that an Arctic ozone hole could develop in the next two decades.

(SOURCE: Schiermeier, Q. 2005. Arctic trends scrutinized as chilly winter destroys ozone. *Science* 435: 6)

Arctic sea ice coverage at record low in 2002
Arctic sea ice extent and area in September 2002 reached their lowest levels recorded since 1978. These conditions likely resulted from anomalous warm southerly winds in spring and persistent low pressure and high temperatures over the Arctic Ocean in summer.

(SOURCE: Serreze, M.C., Maslanik, J.A., Scambos, T.A., Fetterer, F., Stroeve, J., Knowles, K., Fowler, C., Drobot, S., Barry, R.G., and Haran, T.M. 2003. A record minimum Arctic sea ice extent and area in 2002. *Geophys. Res. Lett.* 30:1110, doi:10.1029/2002GL016406)

Increased freshwater flow into the Arctic
Researchers have reported an increase in freshwater discharge in the Arctic of 1,800km^3 per year. The discharges increased threefold in the last 30 years of the 20th century. By comparing the discharge increases in a model that did and a model that did not incorporate greenhouse gas levels, researchers determined this increase in water discharge was definitely linked to greenhouse gas levels and global warming. Via their models, the researchers estimate the discharges will continue to increase until the year 2020. Although freshwater discharges will increase in both hemispheres, rates are higher, due to high levels of warming, in the Arctic. This additional input of freshwater could have major impacts on oceanic circulatory systems, such as the shut down of Thermohaline Circulation in the Atlantic, which in turn could have major impacts on not just the world's marine ecosystems, but also the global climate.

SOUTHERN OCEAN

Habitat protection/degradation

Premature halt in recovery of marine mammals may be due to damaged ecosystems
Antarctic fur seal numbers, after a previously high period of growth, are now stabilising (reaching carrying capacity), despite numbers being an order of magnitude lower than pre-exploitation levels. The authors suggest that 'the near-extinction of parts of various components of the [Antarctic] ecosystem' and population stabilisations are a response to extensive exploitation of marine resources in the Antarctic region. The results of this study imply that lack of recovery in some cetacean populations is due to ecosystem degradation.

(SOURCE: Hucke-Gaete, R., Osman, L.P., Moreno, C.A. and Torres, D. 2004. Examining natural population growth from near extinction: the case of the Antarctic fur seal at the South Shetlands, Antarctica. *Polar Biol.* 27: 304-311)

Sewage pollution around Antarctic research stations
Sewage is not always treated efficiently at some Antarctic bases, and pathogens entering the marine environment 'have the potential to infect and cause disease, or become part of the gut flora of local sea mammal and bird populations'. A sewage treatment facility was installed at Rothera Research Station, a British base on Adelaide Island. As a result of the facility, the sewage plume (and extent of faecal bacteria) in coastal waters was reduced from over 800m, to less than 50m. Sewage treatment facilities are currently only present at a few Antarctic research bases and the author suggests that more should introduce such facilities to reduce human impacts on the otherwise pristine environment.

IUCN Resolution calls for Antarctic marine protected areas
The 3rd IUCN Congress passed a resolution on Antarctica and the Southern Ocean that called for:

> all parties to the Antarctic treaty and The Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR) to develop a network of protected areas with urgency being given to marine habitats, and particularly to provide protection to the Ross Sea with marine protected/special management areas;
>
> all parties to the Antarctic treaty to introduce an Antarctic tourism management scheme;
>
> CCAMLR members to develop and strengthen the precautionary management regime for krill to minimise the impact of krill fishing;
>
> the IUCN Director General to provide resources to actively support the establishment of Antarctic protected areas, to develop liability rules and procedures for environmental damage taking place in the Antarctic Treaty area and to ensure that cumulative environmental impacts are taken into account in decision making;
>
> the IUCN Director General to promote ways to enforce existing measures that manage and protect the Antarctic ecosystem;
>
> the IUCN Director General to assist in raising public awareness of Antarctic environmental issues.

(SOURCE: IUCN 2004. CGR3. RES029-REV1. *Antarctica and the Southern Ocean*. 3rd IUCN Congress, 17-25 November 2004, Bangkok, Thailand)

Exotic species in the Southern Ocean
The introduction of non-indigenous species is a problem in many of the world's oceans and has been identified as a potential threat to Antarctic waters. The examination of vessels travelling between Hobart, Tasmania, and the Southern Ocean revealed the presence of known invasive species among the fouling communities that established themselves on the ships' hulls while at port over winter. The study shows that the global spread of invasive marine species is likely to exert an increasing influence on the biota of the Southern Ocean.

(SOURCE: Lewis, P.N., Hewitt, C.L., Riddle, M., and McMinn, A. 2003. Marine introductions in the Southern ocean: an unrecognized hazard to biodiversity. *Mar. Poll. Bull*. 46: 213-223)

Large ozone hole over Antarctic
The Antarctic ozone 'hole' in 2003 was the second largest ever observed (10.9 million square miles versus 11.5 million square miles in 2000). Chlorine- and bromine-containing compounds from human activity are considered to be the

primary cause of ozone depletion. These ozone-depleting chemicals will remain active in the stratosphere for several decades despite international protocols that have greatly reduced their production and release. Prolonged exposure to ultraviolet B radiation (UVRB), which ozone normally blocks, has been linked to adverse biological effects on plants and animals; for example, on the plankton communities that form the base of the marine food chain in the Southern Ocean.

(SOURCE: Marine Pollution Bulletin News. 2003. *Mar. Poll. Bull*. 46: 1363)

Ultraviolet radiation damages Antarctic marine microbes

Researchers from the Australian Antarctic Division (AAD) have shown that UVBR, beyond impacting phytoplankton, can damage or kill other microbes such as protozoa, bacteria and viruses. Thus, exposure to UVBR due to depletion of ozone in the stratosphere can change the marine microbial community. This impacts the abundance, size structure, palatability and nutritional quality of food within the food web in Antarctic waters.

(SOURCE: Marine Pollution Bulletin News. 2004. *Mar. Poll. Bull*. 49: 373)

Southern Ocean fishing pirates

Illegal fishing has taken a toll on certain fish populations in Antarctic and sub-Antarctic waters. Pirates are now being targeted by the Australian Government, which has committed nearly AU$90 million over two years to improve patrolling in the Southern Ocean and is seeking to secure an agreement with member nations of the CCAMLR. A publicly available, so-called 'ship-of-shame' register has been proposed to allow countries to identify vessels known to be engaged in illegal fishing activities.

(SOURCE: Marine Pollution Bulletin News. 2004. *Mar. Poll. Bull*. 49: 884)

Chemical pollution

Increasing levels of persistent organic pollutants in Antarctic organisms

Levels of POPs continue to increase in the Antarctic due to global redistribution and recent uses in the southern hemisphere. Top predators – Weddell seals and southern elephant seals – biomagnified persistent organic pollutants 30-160 fold relative to their krill prey. Future biomonitoring should include a range of mammal species due to the different ecology and metabolic abilities of each species.

(SOURCE: Goerke, H., Weber, K., Bornemann, H., Ramdohr, S., and Plotz, J.2004. Increasing levels and biomagnification of persistent organic pollutants (POPs) in Antarctic biota. *Mar. Poll. Bull.* 48: 295-302)

Banning TBT versus invasive species: an environmental quandary

As a result of the discovery of high levels of TBT in Antarctic sediments (see Negri *et al.* 2004 below), it has been proposed that TBT anti-fouling paints be banned for Antarctic vessels. However, concerns have also been raised about the possible introduction of invasive species on hulls without anti-fouling treatments, particularly as Antarctic vessels suffer hull abrasion from sea ice. The authors note that there may be particular problems with vessels transiting in other regions of the world and then visiting Antarctica or sub-Antarctic islands briefly (such as re-supply vessels and tourism-related vessels).

(SOURCE: Lewis, P.N., Riddle, M.J. and Hewitt, C.L. 2004. Management of exogenous threats to Antarctica and the sub-Antarctic Islands: balancing risks from TBT and non-indigenous marine organisms. *Mar. Poll. Bull.* 49: 999-1005)

Mercury in the Southern Ocean marine food chain

Antarctic marine biota is generally believed to have relatively low levels of anthropogenic contaminants. Although mantle tissue from deepwater-dwelling warty squid from the Southern Ocean had relatively low levels of mercury, levels in Patagonian toothfish from Macquarie Island were relatively high. Considering that the fish analysed were juveniles and that mercury bioaccumulates, levels in adult fish could be even higher. Mercury levels in some fish were higher than some recommended human health limits. Elevated mercury levels in such fish species is a cause for concern for marine mammals that may be ingesting contaminated species.

MAXIMUM CONTAMINANT LEVELS

Mercury (ng g^{-1}): 590.

(SOURCE: McArthur, T., Butler, E.C.V. and Jackson, G.D. 2003. Mercury in the marine food chain in the Southern Ocean at Macquarie Island: an analysis of a top predator, Patagonian toothfish (*Dissostichus eleginoides*) and a mid-trophic species, the warty squid (*Moroteuthis ingens*). *Polar Biol.* 27: 1-5)

Status of organochlorines in the atmosphere of the Southern Ocean

OC levels measured during a Brazilian Antarctic Expedition in 1995 were compared with earlier data. Both HCH levels and DDT levels were 10 times lower than the previous data of 1987; in the case of DDT, this indicated that any new inputs of DDT have not reached the southwest Atlantic sector of the Antarctic region. Atmospheric PCB levels showed no significant temporal trend and have apparently not decreased rapidly in the last decades.

(SOURCE: Montone, R.C., Taniguchi, S., Boian, C., and Weber, R.R. 2005. PCBs and chlorinated pesticides (DDTs, HCHs and HCB) in the atmosphere of the southwest Atlantic and Antarctic oceans. *Mar. Poll. Bull*. 50(7):778-782)

High levels of tributyltin in Antarctic marine sediments

Nearshore sediment samples were analysed for butyltin (BT) contaminations in the Ross Sea, Antarctica. Tributyltin (TBT) was the predominant contaminant, with levels at some sites considered to be high. The source of BTs could be anti-fouling paints abraded from the surface of ice-breaking ships or from the hulls of grounded vessels (see Lewis *et al.* 2004 above). This is the first time this pollutant, which has been linked to contaminant health risk concerns in cetaceans, has been recorded in the Antarctic.

MAXIMUM CONTAMINANT LEVELS

Total butyltin (ng Sn g^{-1} dry weight): 2290

(SOURCE: Negri, A.P., Hales, L.T., Battershill, C. Wolff, C. and Webster, N.S. 2004. TBT contamination identified in Antarctic marine sediments. *Mar. Poll. Bull.* 48: 1142-1144)

Some organochlorines at equilibrium, others increasing

Between 1987 and 1996, most POP levels showed significant increases in benthos-feeding and fish-feeding fish, while they remained nearly constant or increased less in a krill feeder. Hence, the former species represent indicator species for changing POP levels in Antarctica. By comparison with trends in the Northern Hemisphere, global distribution of HCB appears to be more uniform. Changing levels of other POPs reflect global redistribution and increasing transfer to Southern Ocean waters, probably due to recent usage in the Southern Hemisphere and climate change.

RATIOS (1996/1987) OF AVERAGE CONCENTRATIONS
PCB 138: 0.7; PCB 180: 1.7; PCB 153: 1.8; HCB: 0.8; p,p'-DDE: 2.0; nonachlor III: 2.9; trans-nonachlor: 3.3; mirex: 6.7.

(SOURCE: Weber, K and Goerke, H. 2003. Persistent organic pollutants (POPs) in Antarctic fish: levels, patterns, changes. *Chemosphere* 53: 667-678)

Chemical contamination around Antarctic bases
Several studies examined contaminant levels around Antarctic bases held by New Zealand, Brazil and Australia. Several areas had been contaminated by minor fuel spills, and elevated levels of silver, cadmium, lead, vanadium, boron, molybdenum, nickel, copper, cobalt, phosphate, manganese, magnesium, tin, iron and zinc were found in soils and sediments near the bases. Sources included paints, sewage and contaminant-laced melt water. These studies show the potential for local contamination of the polar environment around Antarctic bases and how this contamination could affect coastal marine species and coastal marine habitats.

Climate change

A massive decrease in krill levels may be due to global warming
Researchers compared Antarctic krill records gathered by nine countries, encompassing data from 12,000 net hauls collected during the period 1926-2003. The results showed an 80% decrease in krill abundance in the last 30 years. The researchers link the decline to loss of winter sea ice (under which krill over-winter) and also global warming. Such a massive reduction in krill stocks has significant implications for Antarctic cetaceans for whom krill is a major prey species. If global warming causes the loss of fast-ice in winter, depletion of the whales' prey base will increase.

(SOURCE: Atkinson, A., Siegel, V., Pakhomov, E., and Rothery, P. 2004. Long-term decline in krill stock and increase in salps within the Southern Ocean. *Nature* 432: 100-103)

Coastal Antarctic glaciers shrinking at an alarming rate
A new survey showed that nearly 90% of the 244 glaciers on the Antarctic Peninsula analysed in the study are losing snow and ice faster than they are being replaced. Researchers from the British-Antarctic and US Geological Surveys compared 2,000 aerial photos of the glaciers taken in the 1940s against 100 recent satellite images. They discovered that the glaciers had grown until the middle of the 20th century, stabilised in the 1960s, and began retreating in the 1970s. The researchers noted that retreat of these glaciers has been rapidly accelerating. One prime example is the Sjogren Glacier, whose edge has moved inland by more than 13km since 1993. Those glaciers that have not retreated (32) have been relatively few in number, and their advance has only been very limited (an average of 300m), with the total glacial shrinkage overwhelming these small advances. The researchers primarily blame global warming for this ice retreat, but also note that other oceanographic and meteorological factors may contribute.

(SOURCE: Cook, A.J., Fox, A.J., Vaughan, D.G. and Ferrigno, J.G. 2005. Retreating glacier fronts on the Antarctic Peninsula over the past half-century. *Science* 308: 541-544)

East Antarctic ice sheet growing; west Antarctic ice sheet thinning
Satellite images have shown that the East Antarctic ice sheet has been growing in thickness by 1.8cm per year (1992-2003), possibly due to increased precipitation resulting from global warming. The increase in ice thickness is estimated to be enough to reduce the rise of sea level by 0.012cm per year. In contrast, the West Antarctic ice sheet is becoming thinner by 0.9cm per year.

(SOURCE: Davis, C.H., Li, Y., McConnell, J.R., Frey, M.M. and Hanna E. 2005. Snowfall-driven growth in East Antarctic ice sheet mitigates recent sea-level rise. *Science* 24 June 1,898-1,901)

Faster flow rate and thinner glaciers in Amundsen Sea
Researchers have confirmed that glaciers flowing into the Amundsen Sea have become progressively thinner over the past 15 years. The speed of glacier flow has also increased. For Pine Island Glacier, this increase in flow extends more than 100km inland, and the rate of flow has increased by 3.5% between April 2001 and early 2003. Warmer water melting the underside of the glacier may be partially causing the increased flow, as well as the disintegration of restraining ice sheets. Currently glaciers are discharging 250 cubic km of ice *per annum* into the Amundsen Sea, a volume 60% greater than is replaced. These processes are contributing more than 10% to the global annual sea-level rise and contributing to oceanographic changes in the Southern Ocean.

(SOURCE: Kerr, R.A. 2004. A bit of icy Antarctica is sliding toward the sea. *Science* 305: 1,897; Thomas, R., Rignot, E., Casassa, G., Kanagaratnam, P., Acuña, C., Akins, T., Brecher, H., Frederick, E., Gogineni, P., Krabill, W., Manizade, S., Ramamoorthy, H., Rivera, A., Russell, R., Sonntag, J., Swift, R., Yungel, J. and Zwally, J. 2004. Accelerated sea-level rise from West Antarctica. *Science* 306: 255-258)

Glacier flow into the Southern Ocean increases after ice shelf collapse
Satellite images of the now-collapsed section of the Larsen B Ice Shelf show that the speed of glaciers emptying into ocean waters has increased from two to six times between January 2000 and February 2003. Decreases in glacier height were also recorded in satellite images after the collapse of the ice shelf: a 38m decrease for one glacier. The study indicates that the ice shelf plays an important role in holding back glaciers; with the breakup of the ice shelf, glaciers and the water they contain are flowing more rapidly into the sea. This has implications for not only decreased water salinity in the region, but also an increase in oceanic water volume, which could ultimately lead to sea level rises.

General

Managing Antarctic tourism
Two Antarctic Treaty Consultative Meetings (ATCM) in 2004 aired concerns about increasing and unregulated tourism in Antarctica. Over the past decade, tourist vessels here have increased in numbers from 12 to 47, with a corresponding dramatic increase in ship-based tourists. Visitors increasingly prefer closer looks on cruise ships and smaller ice-strengthened vessels. The 45 Antarctic Treaty nations are interested in developing an agreed and co-ordinated approach to managing tourism, and an Antarctic tourism industry accreditation scheme is being proposed.

Continued, unregulated growth poses a threat to Antarctica's wilderness and wildlife, which includes cetaceans. This would also have implications for future whalewatching operations here.

POLAR REGIONS

Habitat protection/degradation

Polar ecosystems may be more vulnerable

A review on the environmental problems in polar environments notes that '[e]xtinction of a link in the food chain would be more serious in polar than in other regions, because lower diversity and simpler food chains could mean that elimination of just a single species could have serious structural and functional consequences for food webs'. Due to the large areas over which polar ecosystems extend, immigration or replacement from other regions in the ecosystem may help mitigate against loss of one part of the food chain. However, a counter-argument states that the 'process will…be slowed by the regions' tendency for brooding and direct development of young'.

(SOURCE: Chapman, P.M. and Riddle. M.J. 2005. Toxic effects of contaminants in polar marine environments. *Environ. Sci. Technol.* 39: 200A–207A)

Concerns expressed about future of polar ecosystems

Two researchers for the British Antarctic Survey evaluated threats to polar ecosystems and predicted their possible states by 2025. Although in terms of pollution some polar areas are relatively pristine, there are local problem areas; for example, sites of radioactive dumping and metal processing in the Russian Arctic and organic pollutants associated with military installations and oil installations. Also, ecosystems of both polar areas have been highly disturbed by fishing. Greatest concern was expressed about climate change, particularly reductions in sea ice extent and duration. For Antarctica, although climate change was an issue, more concern was expressed about harvesting of living marine resources. The researchers stated that in both polar areas 'the capacity of marine ecosystems to withstand the cumulative impact of a number of pressures, including climate change, pollution and overexploitation, acting synergistically is of greatest concern'.

(SOURCE: Clarke, A. and Harris, C.M. 2003. Polar marine ecosystems: major threats and future change. *Environ. Conserv.* 30: 1-25)

Polar ecosystem models suggest quick losses and slow recoveries of baleen whales

A Bering Sea ecosystem model predicted that increases in baleen whales might reduce the abundance of Alaska pollock, cephalopods and deep-water fish (through competition for zooplankton), but most other fish groups would not be affected. Total removal of baleen whales caused less than a 10% increase in fish biomass after 100 years. Conversely, reduction in prey species would cause a quick reduction in mammal numbers, which would be slow to recover, even if prey stocks increased. An Antarctic ecosystem model simulated 20th century whaling by removing 10% of baleen whales *per annum* (from 1900 to 1950), followed by 50 years of no whaling. At the end of this 'moratorium', whales had only recovered to 10% of their original (pre-whaling) biomass. The model also simulated the effects on whale stocks of 'culling' other megafauna – only removals of myctophid fish had a major effect (40% increase in whale biomass), although this had a negative impact on seal and penguin populations. The authors concluded that 'environmental effects (which were not modelled) [may] play an important role in influencing the dynamics of marine ecosystems' and 'populations of large whales are easily reduced to low numbers, but take a long, long time to recover'.

(SOURCE: Trites, A.W., Coombs, A.P. and Bredesen, E.L. 2004. Whales, whaling and ecosystem change in the Antarctic and eastern Bering Sea: insights from ecosystem models. *CIESM Mongr.* 25: 85-139)

Chemical pollution

Polar marine ecotoxicology: a lack of information

Ecotoxicology is 'the study of the fate and effects of chemical and physical agents in natural ecosystems'. A series of articles has underlined that there is a lack of data on the toxic effects of such substances on local species in polar regions. Only a few articles are available and many are contained in difficult-to-obtain documents and reports, often restricted to the effects of oil contamination. This recognition is important because the information available from non-polar organisms and habitats may not be applicable to the polar regions. Such knowledge would be crucial for assessing critical doses, instigating appropriate management changes, and mitigating exposure.

(SOURCE: Chapman, P.M. and Riddle, M.J. 2003. Missing and needed: polar marine ecotoxicology. *Mar. Poll. Bull.* 46: 927-928; 2004. Correspondence: *Mar. Poll. Bull.* 49: 603-607)

Pollution issues in polar environments – the need for toxicity, ecological and environmental data

A review noted that polar species have several characteristics that may make them more susceptible to pollutant impacts: relatively long life spans and a tendency toward gigantism (which causes a lower surface-area-to-volume ratio and thus relatively slower rate of contaminant uptake). At the low temperatures typical of polar regions, metabolic rates are also often slower and thus contaminants may accumulate in tissues more slowly. But polar organisms also have high lipid contents for energy storage, thus increasing the risk of lipophilic contaminant uptake. Their lower energy usage may also mean there is less energy available for pollutant detoxification. As species may have longer development times, they may also be exposed for longer periods to contaminants during the vulnerable juvenile period. It was also noted that stressors such as UVBR might work synergistically to intensify pollutant effects. Finally, experimental studies have demonstrated that polar invertebrates may have different sensitivities to contaminants than temperate species, thus making extrapolations of toxicity from temperate species difficult. It is pointed out that much polar contaminant research deals with a simple recording of contaminant values rather than interpreting these values and determining their effects on species and ecosystems. The reviewers conclude, '[t]o adequately address these challenges, we need to undertake more basic research on the ecology of polar marine environments…[to] understand how toxicity is modified under the peculiar conditions characteristic of polar regions'.

(SOURCE: Chapman, P.M. and Riddle, M.J. 2005. Toxic effects of contaminants in polar marine environments. *Environ. Sci. Technol.* 39: 200A–207A)

Climate change

Warning about increased rates of ice sheet disintegration

A review of global warming impacts notes that many climatic change models do not consider increased melting and disintegration of Greenland and Antarctic ice sheets, yet

predict up to an 88cm increase in sea level in the next century due to thermal expansion of water. However, this may be an under-estimation. Approximately 5-10% of the planet's trapped heat went into melting ice in the 20th century, with most of the century's 10-20cm increase in sea level arising from thermal expansion. However, it is possible that, as the atmosphere becomes moister, energy will be more efficiently transported to the polar regions and, as ice streams accelerate, more floating ice will be rafted to warmer waters to melt. The review also highlights the potential for air pollution (particularly 'soot') to hasten melting by decreasing the reflectance, and increasing the absorbance, of heat radiation by water crystals. Glacier melt and ice disintegration could proceed rapidly and, once past a critical point, it would 'be impossible to avoid substantial ice sheet disintegration'. Global warming in excess of 1°C could trigger a runaway melting of the world's ice sheets. Sea level rise and ice sheet changes are important issues for cetaceans, as these could cause major changes in cetacean critical habitat, and critical habitat of prey species, particularly in polar regions.

(SOURCE: Hansen, J. 2005. A slippery slope: how much global warming constitutes 'dangerous anthropogenic interference'? *Clim. Change* 68: 269-279)

Model suggests ice cap melting may not contribute much to sea level rise

A modelling exercise predicted that, due to increased precipitation, sea levels may change by the end of the 21st century from a decrease of 19cm to an increase of 5cm when considering the Antarctic ice sheet and from a 2cm decrease to a 9cm increase when considering the Greenland ice sheet. The total estimated sea level change due to both regions ranged from a 12cm decrease to a 5cm increase. The authors considered thermal expansion of sea water and melting of alpine glaciers as the major sources of sea level rise in the 21st century. However, the researchers note that post-21st century contributions from melting ice sheets could be greater if global warming were to continue.

(SOURCE: Huybrechts, P., Gregory, J., Janssens, I. and Wild, M. 2004. Modelling Antarctic and Greenland volume changes during the 20th and 21st centuries forced by GCM time slice integrations. *Glob. Planet. Change* 42: 83-105)

GLOBAL

Habitat protection/degradation

Floating oceanic plastic debris is widespread

A survey of floating plastic marine debris in the Southern, Atlantic and Arctic Oceans noted such debris in all regions, with rates of 0-10 items km^{-2}, and 3 items km^{-2} even in the Southern Ocean. North of the polar zone, and around the Falkland Islands, densities of debris had increased. In a comparison with a survey conducted ten years earlier in the south-west Atlantic and Southern Oceans, rates of debris encountered were the same. The widespread nature of marine debris, even in 'pristine' environments, is a cause for concern – such debris is known to entangle, or be ingested by, cetaceans. The researchers also point to marine debris as a probable vector of invasive species.

(SOURCE: Barnes, D.K.A. and Milner, P. 2005. Drifting plastic and its consequences for sessile organism dispersal in the Atlantic Ocean. *Mar. Biol.* 146: 815-825)

Reducing whale numbers impacts deep sea species

Researchers have discovered that whale carcasses falling to the deep sea bed can potentially support communities of deep sea organisms for decades. Up to 185 species have so far been identified per large whale skeleton, and at least 32 species are unique to these fallen whale carcasses. However, researchers have expressed concern that past commercial whaling has reduced the number of 'whale falls' and has impacted these deep sea species. Models investigating the impact of reduced whale falls predict that 40% of the North Atlantic whale fall-dependent species have already gone extinct. These results significantly broaden the ecosystem impact that whaling, and decreases in whale numbers, can have.

(SOURCE: Ferber, D. 2005. Whaling endangers more than whales. *Science* 307: 1190-1191)

Fish population collapse and why populations do not recover

An analysis of 230 fish populations showed an 83% reduction from known historic levels. Researchers point out that 'known historic levels' often underestimates true historic population sizes as removals and anthropogenic impacts on stocks may precede known data sets. Few reduced populations have shown recovery even 15 years after the population collapsed, with reductions in fishing pressure being insufficient to promote recovery. Problems that prevent recovery include:

(1) slow response by managers to address depletion;
(2) inability to reduce anthropogenic removals/mortality to zero (e.g. bycatch continues);
(3) public/user-group perceptions that are unsupported by science that delay or alter the nature of the managerial response;
(4) the allee effect (small population sizes lead to proportionally increased rates of predation, reduced mating success and reduced fertility);
(5) reduced numbers of adults increasing inter-specific competition and predation of juveniles;
(6) reduced abundance of top predators causing a shift in ecosystems that may impact recovery;
(7) selective harvesting, where the largest most successful animals are targeted whereas animals with lower fitness stay in the population.

The impacts of inappropriate fisheries management are illustrated by the Canadian stock of Atlantic cod, where within 30 years the stock declined by 99.9% in some areas. The issues covered in this paper are relevant to cetacean species that are dependent on over-fished prey populations.

IUCN Resolution calls for management of unsustainable marine fisheries and harvests

At the 3rd IUCN Congress, a resolution on sustainable management of the High Seas was passed that called for:

(1) members to implement the FAO Code of Conduct for Responsible Fishing and to enforce measures from several international agreements to ensure sustainable use of High Seas marine resources;
(2) the development of new international mechanisms (via UNCLOS) for the governance, management, protection and restoration of marine biodiversity and productivity in the High Seas;
(3) the taking of immediate action to eliminate illegal, unreported and unregulated fishing;
(4) an upgrading of regional fisheries management organisations to adopt procedures that take into account ecosystem-based, precautionary approaches to minimise impacts on marine ecosystems;

(5) investigation into ways to enforce actions on flag states that fail to control domestically registered vessels;
(6) establish a global network of Marine Protected Areas (MPAs) beyond national jurisdictions and to develop scientific and legal bases for their establishment, by 2012;
(7) support of scientific research into high seas biodiversity and ecological processes to ensure the sustainability of human activities.

(SOURCE: IUCN 2004. *Conservation and sustainable management of high seas biodiversity*. CGR3. RES057-REV1. 3rd IUCN Congress, 17-25 November 2004, Bangkok, Thailand)

Millennium Assessment 2005 report highlights unsustainable use of marine ecosystems

At the request of the UN Secretary-General, the Millennium Ecosystem Assessment (MA) was carried out between 2001 and 2005 to assess the consequences of ecosystem change for human well-being and to establish the scientific basis for actions needed to enhance the conservation and sustainable use of ecosystems and their contributions to human well-being. The findings of the MA's report, published in March 2005, include:

(1) the global rate of extinctions in the last century may be up to 1,000 times higher than historical extinction rates calculated from the fossil record;
(2) coastal habitat change and overexploitation of marine ecosystems are qualified as having had a very high – and increasing – impact on biodiversity over the last century;
(3) capture fisheries are operating well beyond sustainable levels to supply current, much less future, demands;
(4) fish biomass targeted in fisheries has decreased by 90-99% of pre-industrial biomass available;
(5) industrial fishing fleets have shifted to fishing farther offshore and in deeper water to meet global demand;
(6) approximately 35% of the world's mangrove areas – representing an important habitat for tropical cetacean prey – has been lost in the 20th century;
(7) models indicate that total input of nitrogen to coastal ecosystems in developing countries will increase by 10-20% by 2030, which will contribute to toxic algal blooms and the formation of oxygen-depleted 'dead zones'.

The report advocates the establishment of marine protected areas and no-take zones.

Tsunami damage extensive throughout Indian Ocean

Early surveys of coral reefs after a massive tsunami hit on 26 December 2004 show damage that was highly variable, with some areas in far better shape than expected, while others were completely decimated. In the Similan Islands of Thailand, only 15% of the area's coral was severely damaged, while other Thai reefs were 'stripped to bare rock'. Satellite images of habitat damage in Aceh, Indonesia, give an indication of the wide-scale coastal damage. Specific marine and coastal habitat impacts include destruction of mangroves, damage to fringing coastal coral reefs, and probable degradation of the Pulau Weh Marine Reserve (3,900ha) and Kepulauan Banyak Marine Recreation Area (227,500ha). In several areas coastal morphology has changed, with the creation of new lagoons and the enlargements of estuary deltas. Large volumes of soil and debris entering the marine environment are likely to cause degradation of coastal habitats, including those of coastal cetaceans. At least one Indo-Pacific hump-backed dolphin (*Sousa chinensis*) was washed inshore by the tsunami; the dolphin was swept into a lagoon in Khao Lak, Thailand, where local authorities and fishermen trapped it with nets and transported it to the sea by truck. The IUCN notes that ecological effects are likely to be severe, although varied, with the pelagic environment likely to be less affected. The tsunami struck ecosystems that in many cases were already stressed by unsustainable resource use, such as over-fishing and habitat destruction. Areas with healthier ecosystems (i.e. intact mangroves) have been less affected. Management actions that strengthen ecosystem health and resilience are essential to aid and speed up recovery and to protect against future tsunamis and earthquakes.

Meeting on ocean acidification

Since the industrial revolution, the pH of the world's oceans has dropped by 0.1 due to increased carbonic acid levels (created by dissolving carbon dioxide). Concerns have been raised that pH levels could drop by 0.5 by 2100, increasing the acidity of the oceans. In August 2004, scientists met in the UK to develop a research plan to investigate this issue, while simultaneously the Royal Society announced that it will be launching an inquiry into the possible ecosystem effects of this increase in acidity. There is concern that increases in acidity could seriously deplete coral and calcareous plankton, which in turn could disrupt oceanic ecosystems and cetacean prey species.

(SOURCE: Schiermeier, Q. 2004. Researchers seek to turn the tide on problem of acid seas. *Nature* 430: 820)

An approach to identifying vulnerable marine areas

A new approach to MPAs emphasises 'sensitivity' (the degree to which marine features respond to stresses) and 'vulnerability' (the probability that a feature will be exposed to a stress to which it is sensitive). The paper uses two whale groups to test their proposed approach, using exposure to noise (via boat traffic and oil production) as the stressor against which the cetaceans are to be protected. Plotting the probability of encountering a stressor against the distribution of the cetaceans, the study determined key marine areas in which the whales would be vulnerable. Humpback whales were predicted to be more vulnerable to small boat traffic, ferry routes and oil production, but they and other balaenopterid whales were both vulnerable to shipping lanes. This paper introduces a potentially useful method for highlighting areas where habitat degradation or environmental threats are greatest and where cetaceans should receive greater protection.

Chemical pollution

Negative effects of contaminants on fertility and reproductive systems

A review on environmental contaminants described impacts on reproductive systems by pollutants, including organic and trace element pollutants, but also metabolic by-products

from female contraceptives. The authors state 'the developmental consequences of environmentally mediated DNA damage to sperm include impaired embryonic development and the induction of abnormalities in the offspring such as childhood or testicular cancer'. Several contaminants that have been detected in cetacean tissues (e.g. PAHs and dioxins) are known to have impacts on fertility and to produce reproductive abnormalities. The effects of possible oestrogen-mimicking chemicals such as DDT, furans, dieldrin and other OCs were also highlighted, but the scale and mechanism of these effects were unclear.

(SOURCE: Aitken, R.J., Koopman, P. and Lewis, S.E.M. 2004. Seeds of concern. *Nature* 432: 48-52)

Biomarkers of contamination studied with non-lethal methods

Effective non-lethal techniques to study the effects of toxic pollutants on marine mammals have been developed in recent years. One such technique is currently being investigated using marine mammal cell lines to test for biomarkers for the highly toxic dioxin class of chemicals. Another is the induction of the cytochrome P450 1A1 enzyme (CYP1A1), which has frequently been used as a biomarker for PCB, dioxins, furans and PAHs in animal tissues, including marine mammals (notably white whales). CYP1A1 induction was effectively done from skin samples collected via biopsies of 50 sperm whales.

Total Environ.* 331: 69-82; Shao, Q., Wilson, M.D., Romanek, S.D. and Hobson, K.A. 2004. Time series analysis of elemental and isotopic data from biomineralized whale tissue. *Environ. Ecol. Stat.* 11: 323-337)

PCBs and DDE damage sperm

Slight negative effects were found by investigating PCB and *p,p'*-DDE levels in the blood of fishermen (consuming varying levels of contaminated fish) and comparing with sperm chromatin/DNA integrity. Thus, organic contaminants can cause infertility via sperm damage, which may have life history and population recovery implications for contaminated cetaceans.

(SOURCE: Rignell-Hydbom, A., Rylander, L., Giwercman, A., Jönsson, B.A.G., Lindh, C., Eleuteri, P., Rescia, M., Leter, G., Cordelli, E., Spano, M. and Hagmar, L. 2005. Exposure to PCNs and *p,p'*-DDE and human sperm chromatin integrity. *Environ. Health Perspec.* 113: 175-179)

Toxic brominated fire retardants (PBDEs) – as big a problem as PCBs

PBDEs, commonly produced as fire retardants, but also found in plastics products, are structurally similar to PCBs. PBDE properties, similar to those of PCBs, can cause hormonal disruption (especially of thyroid hormones) and neurological and developmental abnormalities, and are also mutagenic and carcinogenic. PBDEs have also been discovered in a wide range of aquatic species, including cetaceans, although there appear to be hotspots around developing nations. However, unlike concentrations of PCBs, concentrations of PBDEs are increasing. It is argued that 'PBDEs may surpass PCBs in a few decades to become the most prevalent organohalogen compound', making this class of chemicals a pollutant of concern.

(SOURCE: Tanabe, S. 2004. PBDEs, an emerging group of persistent pollutants. *Mar. Poll. Bull.* 49: 369-370)

Pollutants affect animal behaviour

The endocrine system-disrupting nature of many pollutants can also impact behaviour, particularly mating behaviour or rearing of young, both of which are controlled and moderated by sex hormones. Impacts on thyroid hormones may also affect levels of activity, which in turn may affect the ability to feed. Other behavioural changes in mammals that have been linked to pollutants include increased aggression and retarded learning. Thus, pollutants could have effects that are not directly physiological, but could reduce breeding success and increase mortality rates through behavioural changes. Behaviour could therefore be used as a non-invasive biomonitor for pollutant levels, emphasising the need for development in the new field of 'behavioural ecotoxicology'.

(SOURCE: Zala, Z.M. and Penn, D.J. 2004. Abnormal behaviours induced by chemical pollution: a review of the evidence and new challenges. *Anim. Behav.* 68: 649-664)

Disease and mortality events

Antibiotic resistant bacteria in the aquatic environment

A study on antibiotics in waters discharged from a sewage treatment plant in Brisbane, Australia, determined that three antibiotics could be detected up to 500m from the discharge site. Moreover, bacteria in the treatment plant were resistant to all six of the antibiotics researchers tested. Bacteria collected from discharge waters displayed resistance to two of the antibiotics tested. The increasing prevalence of antibiotics and antibiotic-resistant pathogens in the aquatic environment therefore 'pose[s] a potential threat to ecosystem functions and…human health'.

Marine epidemics may be more widespread and harder to control

A review of epidemiology in the marine environment emphasised that terrestrial epidemiology may not be transferable to the marine environment. Species in marine

ecosystems have more open populations, often with very widespread dispersal patterns, typically via copious volumes of eggs or larvae with adaptations for long-distance dispersal. These factors may make disease transmission more widespread and rapidly propagated. As colonial or modular organisms are more common in marine systems than terrestrial ones, lack of genetic diversity may lead to increased rates of infection. Methods for containing epidemics in terrestrial systems (e.g. quarantine, vaccination, culls, movement restrictions) are generally not, or less, applicable to the marine environment. Several marine diseases in recent years have had terrestrial sources – transmitted to the marine environment by sewage, for example. However, dealing with epidemics in the marine environment requires the development of new epidemiological models and control strategies.

(SOURCE: McCallum, H.I., Kuris, A., Harvell, C.D., Lafferty, K.D., Smith, G.W. and Porter, J. 2004. Does terrestrial epidemiology apply to marine systems? *Trends Ecol. Evol.* 19(11): 585-591)

Blood chemistry values are not a good indicator for health trends

Using bottlenose dolphins as a potential indicator species, researchers developed a list of 19 blood parameters to use as indicators and indices of the 'health' of a population. Suggested blood parameters included alkaline phosphatase, creatine, blood urea and blood cell counts. However, the approach was hampered by inter-laboratory variability and lack of independence between some factors. Comparing stranding rates, losses of known animals, and losses of calves against the blood parameters, a slight positive correlation was obtained, but it was not significant. Although the health status of some individuals could be summarised by the factors, it was suggested that this approach would not be able to detect trends in population health and perhaps more sensitive or additional factors and indicators are required.

Marine mammal cancer link with PCBs

An unusually high number of California sea lions stranded along the central California coast during the period 1993-2003 had cancerous tumours. When compared to sea lions that died from non-cancer-related causes, blubber levels of PCBs in these cancer-stricken animals were significantly higher. This association between blubber concentrations of PCBs and cancer in sea lions suggests that these contaminants may play a role in the development of this disease in marine mammals, including cetaceans.

MAXIMUM CONTAMINANT LEVELS

Blubber (ng g^{-1} wet weight) ΣPCB: 64,000 (males), 39,000 (females); ΣDDT: 200,000 (males), 120,000 (females).

MEDIAN CONTAMINANT LEVELS

Climate change

Gas eruptions may add to global warming and affect ecosystems

Recent discoveries of gas eruptions off the coast of Africa (which in one instance covered an area two-thirds the size of Belgium) has led to concerns about the role of these eruptions in exacerbating global warming. The gas eruptions are primarily the result of upwelling-fueled, very high rates of primary production, which lead to large seabed deposits of organic material. These in turn lead to increased bacterial activity and effervescing gases, including the greenhouse gas methane, which is the predominant product. Global warming may affect wind patterns, which in turn increase the rate of upwelling, which increases the nutrient supply for phytoplankton production. With the production of methane, greenhouse gases increase; this in turn increases the rate of upwelling and so on – a positive-feedback loop. The researchers note that there may be a biological remedy if plankton-eating fish, able to swim against currents, could consume and reduce the phytoplankton levels. The study documents another possible ecosystem-level impact of global warming, which in turn may contribute to global warming itself.

(SOURCE: Bakun, A. and Weeks, S.J. 2004. Greenhouse gas buildup, sardines, submarine eruptions and the possibility of abrupt degradation of intense marine upwelling ecosystems. *Ecology Letters* 7: 1015-1023)

Global warming affecting plankton levels and seasonality

Since 1935, plankton has been collected from devices attached to ocean-going freighters for research purposes. Using the large data set derived from this trawled plankton, it was determined that the abundance of plankton in the northeast Atlantic has shifted over the past 45 years, with increasing phytoplankton abundance in temperate and polar regions, due to warming of surface waters, and decreasing abundance in warmer regions. Moreover, the timing of the seasonal abundance of plankton has also shifted. These changes in phytoplankton abundance are already affecting components of the food web levels, and have been linked to the decline of fish species such as North Sea cod. These ecosystem changes resulting from global warming will have multiple effects on marine mammal stocks and their prey species, globally.

Satellite data confirms that global warming is occurring

Climatologists using data collected from deep oceanic waters and satellite imagery confirm that heat being absorbed by the planet (including by marine waters) exceeds heat radiated into space by 0.85W m^{-2} of the earth's surface, causing a net warming. The analysis predicts a 0.6°C rise in temperature over the next century even if greenhouse gases are capped immediately, and likely sea level rise and further disintegration of polar ice sheets. One of the researchers stated in a newspaper interview that '[t]here can no longer be genuine doubt that human-made gases are the dominant cause of observed warming'.

(SOURCES: Hansen, J., Nazarenko, L., Ruedy, R. Data from space, oceans validate global warming timeline. *Washington Post* 29 April 2005: A13)

Possible reduction in Thermohaline Circulation – a warning for massive changes in climate

The premise of the Hollywood movie 'The Day After Tomorrow' is that global warming leads to the cessation of Thermohaline Circulation (THC) in the North Atlantic, leading to decreased heat exchange from the ocean to the north Atlantic region, thus causing rapid decreases in temperature in the Northern Hemisphere. Scientists studying the flow of water over the Greenland-Scotland ridge warn that changes in water flows and salinities in this region are possibly indicative of a weakening of THC and that this issue urgently needs investigation.

Scientists and policymakers agree on climate change strategies

A report issued by a 14-member independent panel of scientists and policymakers sought to find common ground between nations that have ratified the 1997 Kyoto Protocol and those that have not. Its recommendations include the following:

(1) a long-term objective should be established to prevent global average temperature from rising more than 2°C above the pre-industrial level;
(2) G8 governments should establish national standards to generate at least 25% of electricity from renewable energy sources by 2025;
(3) G8 governments should increase their spending on research, development, and demonstration of advanced technologies for energy-efficient and low- and zero-carbon energy supply two-fold or more by 2010, at the same time as adopting near-term strategies for the large-scale deployment of existing low- and no-carbon technologies;
(4) G8 governments should shift their agricultural subsidies from food crops to biofuels, while implementing appropriate safeguards to ensure sustainable farming methods are encouraged, culturally and ecologically sensitive land preserved, and biodiversity protected;
(5) developed countries should honour existing commitments to provide greater financial and technical assistance to help vulnerable countries adapt to climate change and pursue the establishment of an international compensation fund to support disaster mitigation and preparedness.

Model confirms anthropogenic ocean warming occurring

Earlier research modelled the heating patterns of marine waters, assuming heat entrapment by greenhouse gases and compared these figures with recorded oceanic temperatures. The close match in the results confirms previous models predicting ocean warming as the result of anthropogenic activities, but with greater statistical confidence (>95%).

(SOURCE: Kerr, R.A. 2005. Ocean warming model again points to human touch. *Science* 307: 1190)

Climatic oscillations affect cetacean group sizes

An investigation on climatic factors and cetacean behaviour looked at group size in killer whales in Johnstone Strait, British Columbia, Canada, and in bottlenose dolphins in the Moray Firth, Scotland. The study examined patterns of Pacific and Atlantic salmon abundance, in relation to climatic oscillations, and in turn to cetacean group sizes. The cetaceans tended to occur in smaller groups when salmonids were less abundant, which in turn was linked to climatic oscillations. The study shows that the behavioural ecology of cetaceans may be affected by climate change.

(SOURCE: Lusseau, D., Williams, R., Wilson, B., Grellier, K., Barton, T.R., Hammond, P.S. and Thompson, P.M. 2004. Parallel influence of climate on the behaviour of Pacific killer whales and Atlantic bottlenose dolphins. *Ecol. Lett.* 7: 1068-1076)

Climate change affecting cetacean distribution

From an analysis of stranding records in the UK, researchers noted that strandings of cold-water cetacean species have decreased and records of warm-water species have increased. This trend was also supported by survey data. These results are consistent with a northward shift of warm-water cetacean species, and raise concerns that cooler-water species, such as white-beaked dolphins, may be displaced or become extirpated in certain areas.

(SOURCE: MacLeod, C.D., Bannon, S.M., Pierce, G.J., Schweder, C., Learmouth, J.A., Herman, J.S. and Reid, R.J. 2005. Climate change and the cetacean community of north-west Scotland. *Biol. Conserv.* 124: 477-483)

Temperature and sea level rises predicted to occur even if greenhouse gas production has stabilised

Models were used to estimate probable increases in global temperatures and possible increases in sea level. In the 20th century there was an observed 0.6°C increase in global temperatures and a 10-20cm sea level rise. If greenhouse gas production was immediately stabilised, global temperatures were still predicted to increase 0.4-0.6°C over the next century, with a concomitant 14-16cm minimum increase in sea level. Temperature increase scenarios were 1.1-1.5°C, 1.9-2.6°C, and 2.2-3.5°C, depending on the model used. Likewise, sea level rises were predicted at 13-18cm, 18-25cm, and 19-30cm. For the following century (2100-2200), it was predicted that the increase in temperature would slow: a 0.1-0.3°C over the century, but there would be a 12-21cm sea level rise. A second study looked at the potential longer-term warming that would occur even if greenhouse gas composition was fixed at today's levels – greater than a 1°C increase in temperature by 2400 and 10cm increase in sea level per century. The study also investigated the predicted effects of capping and stabilising current emission levels, and predicting their long term effects: 2-6°C total temperature increase by 2400, with sea levels rising at 25cm per century. Therefore, without a decrease in greenhouse gases, temperature and sea level rises are predicted to be inevitable, with substantial changes even if emissions are controlled and remain at current levels.

(SOURCES: Meehl, G.A., Washington, W.M., Collins, W.D., Arblaster, J.M., Hu, A., Buja, L.E., Strand, W.G. and Teng, H. 2005. How much more global warming and sea level rise? *Science* 307: 1769-1772; Wigley, T.M.L. 2005. The climate change commitment. *Science* 307: 1766-1769)

More heat waves expected in the 21st century

Modelling the incidences of heat waves and atmospheric conditions showed that recent heat waves in Europe and North America coincided with an atmospheric circulation pattern that will intensify with increasing emissions of greenhouse gases. This will lead to more frequent, more intense and longer-lasting heat waves in parts of the world. The increasing heat waves could result in indirect impacts on cetaceans that dwell in temperature-sensitive habitats or have temperature-dependent distributions.

(SOURCE: Meehl, G.A. and Tebaldi, C. 2004. More intense, more frequent, and longer lasting heat waves in the 21st Century. S*cience* 305: 994-997)

Estimates of global warming double

Since 1991, the UN Intergovernmental Panel on Climate Change (IPCC) report has predicted a 1.5-4.5°C increase in average temperatures with every doubling of CO_2 levels. However, new results from computer models suggest that the temperature increase could go as high as 11°C. Researchers enlisted 95,000 people from 150 countries to download a general circulation model (GCM) and run it using the idle processing capacity on their personal computers. After analysing 2000 simulations, researchers discovered that when CO_2 concentration doubles from pre-industrial levels – as is expected to happen between 2050 and 2100 – the simulations predict a 1.9 to 11.5°C temperature rise.

(SOURCE: Pelley, J. 2005. Estimates of greenhouse warming double. *Environ. Sci. Tech.* 39: 190A)

Global warming changing fish distribution

A 1°C temperature increase has been witnessed in the North Sea between 1977 and 2001. Fisheries data indicate that this warming water over the past quarter of a century has pushed North Sea fish populations northwards and into deeper waters. The shift in distribution may hamper the recovery of depleted fish stocks in this area and disrupt the North Sea ecosystem. For example, it may introduce new predators or prey into the area. This paper demonstrates the impact of climate change on the distribution of fish stocks, and therefore cetacean prey, as well as how climate change contributes to the decline, or prevents the recovery, of fish stocks.

Hottest summer in Europe result of human influence

Summer 2003 was possibly the hottest in Europe since 1500AD. Researchers analysing recorded European temperature trends in conjunction with models on greenhouse accumulation in the atmosphere and other factors determined (with confidence >90%) that 'human influence has at least doubled the risk of a heat wave'. If high summer temperatures as observed in 2003 were to become more common, then it could have major impacts on species whose distribution is affected by temperature (such as many cetaceans).

(SOURCE: Stott, P.A., Stone, D.A. and Allen, M.R. 2004. Human contribution to the European heat wave of 2003. *Nature* 432: 610-614).

Noise impacts

ACCOBAMS passes resolution on noise

At the Second Meeting of the ACCOBAMS Contracting Parties, which was held 9-12 November 2004, in Palma de Mallorca, Spain, a resolution was passed that urged all to 'avoid the use of man made noise in habitat of vulnerable species and areas where marine mammals or endangered species may be concentrated' and for noise-producing activities to only proceed with 'special caution' in areas where there may be beaked whales. The resolution also charged the ACCOBAMS Scientific Committee to develop 'a common set of guidelines on conducting activities known to produce underwater sound with the potential to cause adverse effects on cetaceans', including military sonar, and also called for 'extreme caution' when conducting noise-producing activities in the Mediterranean and Black Seas.

(SOURCE: ACCOBAMS. 2004. Assessment and impact assessment of man-made noise. Resolution 2.16. 2nd Meeting of the ACCOBAMS Contracting Parties**,** 9-12 November 2004, Palma de Mallorca, Spain, *http://www.accobams.mc/Accob/Wacco.nsf/0/491fb7e7d4267c0cc1256f7e004b4ec8/$FILE/E%20Res%202.16.pdf*)

Vulnerable animals may not react to human disturbance

Recent research into the disturbance reactions of birds may have implications for the observation of noise-related effects on marine mammals. In an experiment in which turnstones were given supplementary levels of food (controls were not manipulated), these birds showed a greater response to human disturbance, including greater displacement as the result of anthropogenic activity. The implication is that animals that are better fed, or in better condition, can stop feeding sooner and move farther from habitats when disturbed than animals that are in marginal condition. The researchers point out the need to consider the animals that are at greatest risk, rather than the animals that show the greatest reaction, when evaluating human disturbance, i.e. less response to anthropogenic activities does not necessarily mean less impact on animals. It may be more relevant to examine stress and resource use rather than behavioural responses as a measure of vulnerability.

(SOURCE: Beale, C.M. and Monaghan, P. 2004. Behavioural responses to human disturbance: a matter of choice? *Anim. Behav.* 68: 1065-1069)

Dolphin whistling rates increase when boats approach

In Sarasota, Florida, bottlenose dolphins were estimated to encounter a boat within 100m every 6mins during the daytime. Animals produced signature whistles more frequently when a boat approached. It was suggested that these whistles reflect heightened arousal, or bring groups together. The study also noted that jet-driven watercraft were quieter than conventional boats, and idling and ploughing boats were quieter than planing boats.

(SOURCE: Buckstaff, K.C. 2004. Effects of watercraft noise on the acoustic behaviour of bottlenose dolphins, *Tursiops truncatus*, in Sarasota Bay, Florida. *Mar. Mamm. Sci*. 20: 709-725)

Exposure to noise caused retarded development in hearing centres of brain

A study investigating brain development in rats noted that animals reared in an environment where they were continuously exposed to moderate levels of noise displayed retarded development of auditory centres of the brain. The researchers note that if this were the case for humans, children reared in a noisy environment could exhibit hearing and linguistic difficulties. If a similar effect occurred in cetaceans, the increasing levels of anthropogenic background noise in the oceans could cause retardation in brain development for functions that are essential to cetacean survival.

Beaked whale mass stranding linked to sonar in the Canary Islands

In July 2004, an 'atypical' mass stranding of four Cuvier's beaked whales occurred in the Canary Islands. There have been at least four mass strandings of beaked whales that have been associated with military exercises conducted near the Canary Islands (1985, 1986, 1987 and 2002). The 2004 mass stranding event coincided with the naval exercise 'Majestic Eagle', which was conducted 100km to the north of the islands in the week prior to the beaked whale carcasses being discovered. Fat emboli, i.e. lesions associated with decompression sickness that have been associated with sonar-linked strandings, were found in the tissues of three of the whales.

(SOURCE: Espinosa, A., Arbelo, M., Castro, P., Martín, V., Gallardo, T. and Fernández, A. 2005. New beaked whale mass stranding in Canary Islands associated with naval military excercises (Majestic Eagle 2004). European Parliament Resolution on noise and sonar

On 28 October 2004, the European Parliament passed a resolution that called on the Commission and Member States to:

(1) 'adopt a moratorium on the deployment of high-intensity active naval sonars until a global assessment of their cumulative environmental impact on marine mammals, fish and other marine life has been completed';
(2) 'immediately restrict the use of high-intensity active naval sonars in waters falling under their jurisdiction';
(3) 'monitor and investigate in a transparent manner mass strandings and deaths of marine mammals in EU waters that are associated with the use of intense anthropogenic noise';
(4) 'conduct a study of the potential impact on the marine environment of the deployment of high-intensity active naval sonars and to provide an assessment, on the basis of information from the Member States, of the impact of current practices in European waters';
(5) 'set up a Multinational Task Force to develop international agreements regulating noise levels in the world's oceans, with a view to regulating and limiting the adverse impact of anthropogenic sonars on marine mammals and fish'.

Also the European Parliament stated it '[c]onsiders that any measures to introduce common standards and cooperation in the defence industry field must exclude and actively seek alternatives to technologies which are likely to cause unnecessary and serious damage to the environment and other Community interests, such as, in this case, fisheries'.

(SOURCE: European Parliament resolution on the environmental effects of high-intensity active naval sonars [B6-0089/2004]), *http://www.animalwelfare.com/whales/Noise/IONC/Docs/EU_Res_2004.pdf*).

IUCN Resolution calls for reduction and regulation of underwater noise

At the 3rd IUCN Congress, a resolution on underwater noise was passed that called for:

(1) the IUCN Director General and IUCN members to identify and implement measures to reduce anthropogenic noise in the world's oceans;
(2) members to conduct further research on the effects of anthropogenic underwater noise on marine wildlife and how to mitigate these effects;
(3) members to recognise that conservation measures should not be postponed due to a lack of full scientific certainty;
(4) the World Commission on Protected Areas (WCPA) to consider anthropogenic noise when working on the designation and management of MPAs;
(5) the Commission on Environmental Law (CEL) to make recommendations on the international regulation of underwater noise;
(6) the development of alternative technologies to reduce marine noise impacts;
(7) restricting the use of military sonar to low-risk areas and work towards regulation of its use.

Cetacean 'milling event' in Hawaii linked to military activities

At 07:30 on 3 July 2004, approximately 200 melon-headed whales were found milling in shallow water in Hanalei Bay, Kauai, Hawaii. Coincident with this event, the US Navy, along with Japanese vessels, was conducting manoeuvres, with active sonar in use, in waters near the island. One whale eventually stranded. This is the first record of this species coming inshore coincident with the use of military sonar.

(SOURCE: Kaufman, M. 2004. Sonar used before whales hit shore. *Washington Post* 31 August 2004: A3)

Multi-species mass stranding in North Carolina linked to military activities

Between 15 and 16 January 2005, 31 short-finned pilot whales, one common minke whale, and two pygmy sperm whales stranded in the Outer Banks area, North Carolina. Coincident with the stranding, six US Navy vessels were operating off Norfolk, Virginia. Although the US Navy stated 'no Navy ships were using active sonar within a 50 nautical miles radius' of the area, one naval vessel did use sonar for seven minutes about 90 nautical miles southeast of the stranding area. The US Navy is currently considering locating a sonar testing range in the waters off North Carolina. This is yet another multi-species cetacean stranding event that has been linked to military sonar use.

(SOURCE: Kaufman, M. 2005. Whale stranding in N.C. followed Navy sonar use. *Washington Post* 28 January 2005: A3)

Riverine Irrawaddy dolphins show greater reactions to boat traffic

Coastal and riverine Irrawaddy dolphins (*Orcaella brevirostris*) decreased surfacing in reaction to the presence of boats. This reaction was more pronounced in riverine animals. While coastal animals only demonstrated reactions to speedboats, riverine animals also showed reactions to motorised canoes and tug boats. Distances at which reactions were caused were also greater for riverine animals (250-300m) than coastal animals (50m). Concern was expressed that boat traffic may be a particular problem for riverine dolphins.

(SOURCE: Kreb, D. and Rahadi, K.D. 2004. Living under an aquatic freeway: effects of boats on Irawaddy dolphins (*Orcaella brevirostris*) in a coastal and riverine environment in Indonesia. *Aquat. Mamm.* 30: 363-375)

Acoustic harassment devices produce high source levels and cetacean-used frequencies in field

Acoustic harassment devices (AHDs or seal scrammers) have been highlighted as a source of anthropogenic sound that may disturb or displace cetaceans, particularly harbour porpoises. A recent study evaluated the source levels of three common varieties of AHDs within an open water setting. Peak source levels ranged up to 193 dB re 1μPa with mid to high frequency (1.8kHz-103kHz) components. The frequencies used in these devices coincide with frequencies used by many cetacean species and at levels that would be likely to cause at least behavioural disturbance and possibly habitat displacement. This emphasises that users of AHDs should consider the unintended impact of these devices on cetaceans.

(SOURCE: Lepper, P.A., Turner, V.L.G., Goodson, A.D. and Black, K.D. 2004. Source levels and spectra emitted by three commercial aquaculture anti-predation devices. In: *Proceedings of the Seventh European Conference on Underwater Acoustics, ECUA 2004, Delft, The Netherlands, 5-8 July, 2004*)

Seismic surveys implicated in giant squid deaths

Concerns have been raised that high rates of giant squid strandings on the northern coast of Spain, adjacent to the Bay of Biscay, may be linked to seismic surveys. Nine giant squid have stranded in this area coincident with seismic surveys, five within a 10-day period in 2001 and four within one week in 2003. All the squid showed evidenced of acoustic trauma, and some with other internal tissue damage. This finding is particularly relevant to cetaceans, as large squid are important prey species of sperm and beaked whales. In addition, the Bay of Biscay is one of the most important habitats for cetaceans in southern Europe, especially beaked whale species.

(SOURCE: MacKenzie, D. 2004. Seismic surveys may kill giant squid. *New Sci.* 184(2467): 15)

Sperm whales show signs of decompression sickness

Examination of sperm whale bones collected over a 111-year time span showed routine osteonecrosis, increasing with age, a symptom in humans of decompression sickness ('the bends'). This indicates that sperm whales are neither anatomically nor physiologically immune to the effects of deep diving. The authors suggest that recent reports of decompression-like sickness in another deep-diving taxon (beaked whales) in the presence of anthropogenic sound sources could therefore be a result of the animals' decompression sickness-avoidance behaviour being overridden by extended periods at the surface to escape the noise.

(SOURCE: Moore, M.J. and Early, G.A. 2004. Cumulative sperm whale bone damage and the bends. *Science* 306: 2215)

Biologically significant effects of noise: recommendations

To address concerns about marine mammal populations and ocean noise, the report of the US National Research Council's Committee on Characterizing Biologically Significant Marine Mammal Behavior made several recommendations, including:

(1) developing a centralised database of marine mammal sightings and the mammals' responses to anthropogenic sound. Surveys should use standardised formats to allow comparison of data, and include track lines, with all data entered into the database to be assessed for quality;
(2) developing a conceptual model to assess the impacts of acoustic activities on marine mammals, with an appropriate sensitivity analysis of the model to identify data needed and to focus research on acquiring the required data;
(3) the use of glucocorticoid and other blood hormone levels to assess stress in marine mammals, and to investigate the effect of age, sex and condition differences. The use of faecal samples to assess stress levels was recommended;
(4) analysing in detail cetacean populations for which there are long-term data sets and develop a set of both individual-based and demographic models;
(5) develop a practical process though which acoustic activities can be assessed to determine whether there will be an adverse effect on marine mammals, which should ideally be precautionary, capable of reassessing risk estimates as data improve, consider the cumulative effect of multiple low-level effects and be composed of a few easy-to-estimate parameters;
(6) a better process to fully consider cumulative impacts and total mortality/losses from all sources.

(SOURCE: National Research Council. 2005. *Marine Mammal Populations and Ocean Noise: Determining When Noise Causes Biologically Significant Effects.* National Academies Press, Washington, DC)

Offshore windfarms could have significant noise impacts

A study funded by the Crown Estate (a UK statutory authority) investigated the possible effects on cetaceans and marine fish from noise and vibrations of offshore windfarms. The study report determined that there would be significant effects during construction, notably during pile-driving. Disturbance reactions (avoidance) would be likely to a distance of several kilometres and severe acoustic trauma was possible within 100m of a site.

(SOURCE: Nedwell, J. and Howell, D. 2004. *A review of offshore windfarm related underwater noises*. Report 544 R 0308. Subacoustec, Southampton; Nedwell, J., Langworthy, J. and Howell, D. 2003. *Assessment of sub-sea acoustic noise and vibration from offshore wind turbines and its impact on marine wildlife; initial measurements of underwater noise during construction of offshore windfarms and comparison with background noise*. Report 544 R 0424. Subacoustec, Southampton)

Mass strandings in the Galápagos – a possible link to noise

A review of cetacean strandings and discovered remains on the Galápagos Islands documented two Cuvier's beaked whale and two short-finned pilot whale mass strandings. Remains of multiple individuals found in the same location also suggest that there have been mass strandings of false killer whales (*Pseudorca crassidens*), pantropical spotted dolphins (*Stenella attenuata*), common bottlenose dolphins and additional mass strandings of pilot whales. One of the beaked whale strandings occurred on 11 April 2000 and was coincident with seismic surveys being conducted by the *Maurice Ewing* research vessel, although the vessel was 270 nautical miles away from the stranding location. The authors postulated that other mass strandings on the Galápagos may be linked to anthropogenic noise, as well as other anthropogenic causes.

(SOURCE: Palacios, D.M., Salazar, S.K. and Day, D. 2005. Cetacean remains and strandings in the Galápagos Islands, 1923-2003. *Latin. Amer. J. Aquat. Mamm.* 3: 127-150)

Pollutant (TBT) may cause hearing loss

Concentrations of TBT have been linked to hearing-inhibiting effects in the inner ear of mammals. Researchers have shown particular concern for the implications for cetaceans: 'Notably, this observation identifies a new environmental threat for marine mammals by TBT, which is known to accumulate in the food chain'. TBT contamination has been highlighted as being an issue for concern in cetaceans, and hearing loss associated with this pollutant could have impacts with respect to whales detecting shipping traffic, the cumulative impact of noise in the oceans and ultimately biologically significant effects on the ability of cetaceans to communicate and detect prey.

Shipping noise symposium report

The first international symposium on 'Shipping Noise and Marine Mammals' was held on 18-19 May 2004 in Arlington, Virginia, USA. This meeting brought together representatives of various ocean industries, academia and other research organisations, government and military personnel, and non-governmental organisations to address, for the first time, the issue of shipping noise and its impact and influence on the marine environment. The main purpose of the meeting was to initiate discussion on what information is available and needed concerning sounds produced by large ships and other vessels and their potential impacts on marine mammals. The issue will only become more urgent – the world's shipping fleet continues to increase in size (number and overall tonnage) and an approximate doubling in the number of large vessels is expected in the next two or three decades. While the relative contribution of sounds from various vessel types to overall ambient noise and their possible impacts on marine life remain largely unknown, quieting technologies do exist and are being further developed by the military and industry. At the conclusion of the meeting, a steering committee was formed to plan a proposed follow-on symposium.

Seismic survey noise travels farther in shallow water

Modelling of the sound propagation of seismic airgun noise predicted noise levels of 160dB re 1μPa at 9km from a 20-gun array (6.5km for a 10-gun array). For 180dB the range was just below 1km (0.95km for a 20-gun array; 0.83km for a 10-gun array). When field measurements were made in deeper water (>300m), however, 160dB was measured at approximately 2.5km, whereas in shallow water, 160dB was received at greater distances than predicted (at least 12km from the array). This paper illustrates the potential noise levels produced from a research vessel conducting seismic surveys, and illustrates the importance of in-field verification of noise levels, and how these may differ substantially from those estimated by predictive models.

(SOURCE: Tolstoy, M., Diebold, J.B., Webb, S.C., Bohnenstiehl, D.R., Chapp, E., Holmes, R.C. and Rawson, M. 2004. Broadband calibration of R/V *Ewing* seismic sources. *Geophys. Res. Lett.* 31: L14310)

Mass stranding in Florida linked to military activities

At the beginning of March 2005, nearly 80 rough-toothed dolphins (*Steno bredanensis*) stranded in the Florida Keys. The mass stranding was coincident with a US Navy submarine exercise in the area. The submarine in question was said to be using two types of active sonar. This is yet another stranding event coincident with a military exercise, involving a pelagic cetacean species not previously observed to strand coincident with acoustic activity.

(SOURCE: Washington Post. 2005. Dolphin troubles may be related to sonar. *Washington Post* 11 March 2005: C12)

General

Nations agree to reduce rate of biodiversity loss by 2010

In April 2002, the 188 parties to the Convention on Biological Diversity agreed to reduce the rate of biodiversity loss significantly by 2010. This commitment was endorsed by the World Summit on Sustainable Development later that year. Measuring progress toward this goal poses a significant challenge. A Red List Index has been proposed to measure changes in overall extinction risk for all species, worldwide, in an entire class of organisms. It has both fine ecological resolution and the ability to represent comprehensive geographical regions. The cost is a lack of the sharp temporal resolution achieved by habitat, population and trophic indices. Other indicators of biodiversity, such as water quality and population trends, will also be measured in an effort to mark progress. Ultimately, urgent investment of resources is needed to ensure the goal is met.

(SOURCE: Brooks, T. and Kennedy, E. 2004. Biodiversity barometers. *Nature* 431: 1046)

Record mortality in endangered North Atlantic right whales

Since February 2004, at least seven right whales have been found dead along the US east coast. The vast majority of these mortalities are anthropogenic and represent more than 2% the population, which is already in decline. The deaths are as follows:

(1) 3 February 2004: A pregnant female and her near-term calf were killed by a ship and found floating east of Virginia Beach, Virginia along their migratory corridor.
(2) 7 February 2004: A young calf was found dead of undetermined causes in the southeastern US calving ground.
(3) 17 November 2004: A US Naval vessel struck a pregnant female, her body and that of her near-term female calf were found on 24 November off the coast of Virginia.
(4) 9 December 2004: The body of a dead right whale was reported floating off Nantucket Island in Massachusetts, bad weather prevented researchers from retrieving the body and no cause of death was determined.
(5) 10 January 2005: The body of a female right whale was seen floating off Nantucket Island. Bad weather prevented researchers from retrieving her body and no cause of death could be determined, nor could it be determined whether this mother of six previous calves was pregnant.
(6) 25 January 2005: The body of a female and her near-term calf were found in the calving ground off the coast of Georgia. This was her first calf and the strain of the pregnancy caused the scars from a previous anthropogenic injury to re-open, resulting in her death and that of her calf.
(7) 4 March 2005: The body of an adult right whale was found on an island off the coast of Virginia. The death resulted from a serious injury consequent to the animal's entanglement in fishing gear. Identity of the animal is pending.

ACKNOWLEDGEMENTS

The editors would like to thank David Janiger for his notifications on recently published papers and supplying pdf copies of papers that were difficult for us to obtain. We would also like to thank Sarah Dolman, Steve Isaac, Peggy Krahn, Sue Moore, Todd O'Hara, and Sharon Young for submitting items in response to our solicitation for SOCER submissions. The authors also wish to thank the Government of Austria and Humane Society International for continuing to provide support for SOCER preparation, as requested by Resolution 2000-7.

GLOSSARY

Species			
Beluga whale	*Delphinapterus leucas*	Atlantic salmon	*Salmo salar*
Bowhead whale	*Balaena mysticetus*	Giant squid	*Architeuthis* spp.
Cuvier's beaked whale	*Ziphius cavirostris*	Pacific cod	*Gadus macrocephalus*
Common bottlenose dolphin	*Tursiops truncatus*	Pacific salmon:	
False killer whale	*Pseudorca crassidens*	Chinook	*Oncorhynchus tshawytscha*
Harbour porpoise	*Phocoena phocoena*	Sockeye	*Oncorhynchus nerka*
Humpback whale	*Megaptera novaeangliae*	Coho	*Oncorhynchus kisutch*
Indo-Pacific humpback dolphin	*Sousa chinensis*	Pink	*Oncorhynchus gorbuscha*
Irrawaddy dolphin	*Orcaella brevirostris*	Chum	*Oncorhynchus keta*
Killer whale	*Orcinus orca*	Patagonian toothfish	*Dissostichus eleginoides*
Long-finned pilot whale	*Globicephala melas*	Walleye pollock	*Theragra chalcogramma*
Melon headed whale	*Peponocephala electra*	Warty squid	*Moroteuthis ingens*
Minke whale	*Balaenoptera acutorostrata*	Krill	*Euphausia superba*
Narwhal	*Monodon monoceros*		
North Atlantic right whale	*Eubalaena glacialis*	**Elements**	
Northern minke whale	*Balaenoptera acutorostrata*	Ag	Silver
Pantropical spotted dolphin	*Stenella attenuata*	Al	Aluminium
Pygmy sperm whale	*Kogia breviceps*	As	Arsenic
Rough-toothed dolphin	*Steno bredanensis*	B	Boron
Short-finned pilot whale	*Globicephala macrorhynchus*	Cd	Cadmium
Sperm whale	*Physeter macrocephalus*	Co	Cobalt
White-beaked dolphin	*Lagenorhynchus albirostris*	Cr	Chromium
Antarctic fur seal	*Arctocephalus gazella*	Cu	Copper
California sea lion	*Zalophus californianus*	Fe	Iron
Harbour seal	*Phoca vitulina*	Hg	Mercury
Hawaiian monk seal	*Monachus schauinslandi*	N	Nitrogen
Mediterranean monk seal	*Monachus monachus*	K	Potassium
Polar bear	*Ursus maritimus*	Mg	Magnesium
Ringed seal	*Phoca hispida*	Mn	Manganese
Southern elephant seal	*Mirounga leonina*	Mo	Molybdenum
Weddell seal	*Leptychotes weddelli*	Ni	Nickel
Rat	*Rattus norvegicus*	Pb	Lead
Turnstone	*Arenaria interpres*	Se	Selenium
Alaska pollock	*Theragra chalcogramma*	Sn	Tin
Arctic cod	*Boreogadus saida*	V	Vanadium
Atlantic cod	*Gadus morhua*	Zn	Zinc

Terms

ACCOBAMS: Agreement on the Conservation of Cetaceans of the Black Sea, Mediterranean Sea and Contiguous Atlantic Area.

Acoustic harassment devices: Also known as AHDs or seal scrammers. These are devices that produce high intensity sound and are designed to displace marine mammals such as seals from areas such as fish farms.

Aquaculture: Finfish or shellfish farming.

Anti-fouling paint: Paint used to prevent accumulation of marine organisms, such as barnacles, on ship hulls. Repulsing chemicals such as butyltin are used to prevent organisms from settling.

Atypical mass stranding: A stranding involving more than two beaked whales that strand more or less simultaneously in time, but in locations separated by at least a kilometre or more.

Benthic: Referring to the ocean bottom.

Bioaccumulation: Increase in concentration of a contaminant in an organism's tissues (e.g. blubber) over time, compared to the concentration of the contaminant in the environment.

Biomagnification: Increase in concentration of a contaminant from one link in a food chain to another.

Biomarkers: A biological indicator, e.g. blood chemical levels, of health status or pollutant level.

Biopsy: Removal of tissue or cells from the living body for non-lethal examination or study, especially for diagnostic purposes.

Biota: All living things in an ecosystem.

Brominated: Containing the element bromine.

Butyltin: An organic compound containing tin that has toxic properties to marine life, used in anti-fouling paints on ship hulls.

Carcinogenic: Capable of causing cancer.

CFC: Chlorofluorocarbons.

Chlordane: An organochlorine pesticide.

CO_2: Carbon dioxide, a major 'greenhouse' gas.

dB: Decibel – a measure of sound pressure level.

DDE: The organochlorine dichlorodiphenylethane, a product of the breakdown of DDT.

DDT: The organochlorine pesticide dichlorodiphenyltrichloroethane, which tends to accumulate in the ecosystem and in the blubber and certain internal organs of cetaceans.

Dioxin: A class of extremely toxic organochlorines, generally produced as a waste or byproduct.

Dry weight: Dry weight, as opposed to wet weight, is a basis of measurement whereby concentrations of a substance are compared with dry content (i.e. all water is removed) of a material.

Endocrine system: A system of ductless glands producing hormones that control and moderate metabolic processes in the body.

Epidemic: The outbreak of a pathogen- or parasite-caused disease in a population that increases rapidly, reaches a peak then declines. The term epizootic is used for non-human animals.

Epidemiology: The study of disease epidemics (c.f.)

Exogenous: Derived or existing externally.

Fluorinated: Containing the element fluorine.

HCB: Hexachlorobenzene, an environmentally persistent organochlorine pesticide.

HCH: Hexochlorocyclohexane, an environmentally persistent organochlorine pesticide.

Hz: Hertz, a measure of sound frequency (pitch), in wave cycles per second (kHz = 1000 Hertz).

Immunosuppression: The suppression of the immune system or response, resulting in a greater susceptibility to disease.

Lipid weight: A basis of measurement whereby concentrations of a substance are compared to the lipid (fat) content of a material.

Lipophilic: A reference to compounds that dissolve easily in lipid (i.e. dissolve and accumulate in fat cells).

Mutagenic: Capable of causing genetic mutations.

Myctophid: Of the family Myctophidae, a taxon of deep sea fishes comprising the lanternfish.

Organochlorine: Organic compounds that contain chlorine. Many are toxic and used as pesticides. Most of these compounds persist in the environment (are not biodegradable) and also tend to accumulate in fatty tissue (e.g. blubber) of cetaceans and other marine organisms.

Osteonecrosis: Death of bone tissue.

Ozone: O_3, a molecule naturally occurring in the upper atmosphere that filters ultraviolet radiation.

PAHs: Polycyclic aromatic hydrocarbons.

Pathogen: A disease-causing agent (e.g. bacterium, virus).

PCB: Polychlorinated biphenyls (209 different forms that contain differing numbers of chlorine atoms arranged in various positions on the aromatic rings) are industrial organochlorines that were manufactured to be used in electrical transformers and other applications. These man-

made chemicals do not occur naturally and all traces reflect pollution.

Pelagic: Referring to open water, free-swimming marine species.

Perfluorinated organochemicals (PFOs): A class of toxic organic molecules with fluorine atoms attached (also called perfluorinated compounds), including perfluoroalkyl carboxylates (PFCAs) and perfluoro-octane sulfonate (PFOS).

Phagocytosis: A cell's ability to digest (remove) extracellular molecules.

Phytoplankton: Free-floating marine plants (versus zooplankton – free-floating marine animals).

Polychlorinated naphthalenes: A group of chemicals containing 1-8 chlorine atoms bound to the naphthalene di-benzene ring, structurally similar to PCBs.

TBT: Tributyltin – a toxic chemical commonly used in anti-fouling paints on ship hulls.

TEQ: Toxic Equivalent. The overall toxicity or environmental threat posed by a set of closely related pollutants.

Thermohaline Circulation: The deepwater circulation of the oceans, which is primarily caused by differences in density (which are in turn dependent on salinity and temperature) between water bodies of different regions. This circulation system is important in distributing heat energy around the world.

Trophic level: Each level of consumption in a food chain.

Watt: A measure of electrical energy.

Wet weight: See dry weight.

Zoonotic: Animal disease that is capable of infecting and causing disease in humans.

Appendix 3

SEISMIC SURVEYS AND THEIR POTENTIAL IMPACTS TO CETACEANS: A PROPOSED PRE-SC MEETING WORKSHOP FOR THE ENVIRONMENTAL CONCERNS STANDING WORKING GROUP AT SC/58

Steering Committee: Rosenbaum (Chair), Findlay, Moore, Rojas-Bracho, Rowles, Simmonds, Williams.

Rationale and justification

Marine seismic surveys are carried out to identify the geological structures indicative of potential oil and gas deposits below the seabed or for monitoring of reservoirs after production is underway[1]. High intensity sound pulses (termed 'shots') are produced by airguns (usually in series) near the surface, and are directed through the water and into the seafloor where they are reflected by geological discontinuities. The horizontal sound fields produced by airgun arrays have potential to impact cetaceans. Received levels a few kilometres from the source can exceed 160dB, and behavioural responses by cetaceans have been shown to occur tens of kilometres from the source (McCauley *et al.*, 2000). However, many aspects of the horizontal sound field from airgun arrays are still not well described.

The potential for seismic surveys to impact cetaceans is a cause of concern. Reactions of cetaceans to underwater noise and other human-related activities are highly variable, and may range from no detectable response to active avoidance or direct displacement (reviewed in Richardson *et al.*, 1995 but see Weller *et al.*, 2002). The longer-term and cumulative effects of noise and disturbance related to seismic surveys are unknown. An apparent tolerance (habituation) to noise does not necessarily indicate that there are no deleterious effects.

The scientific and conservation community has expressed concerns about the potential effects on whale populations and other cetaceans due to noise exposure from seismic surveys. Potential impacts of seismic surveys on cetaceans include but are not limited to behavioural, auditory, stress-related response, and long-term/cumulative effects at the individual and population level. Of equal concern is the general lack of effective mitigation and monitoring during planning, operations, and close-out phases.

A two-day pre-meeting workshop is proposed to address these concerns as part of the Environmental Concerns SWG at SC/58 (IWC, 2005). Tentative dates are May 20-21 2006. The workshop is timely, as these issues are being raised among national US and UK management organisations (MMC and JNCC) and at other regional scales. The SC is in a position to synthesise and evaluate the relevant information on this issue and provide the appropriate recommendations. The 'Seismic Workshop' will take place as an SC/58 pre-meeting Workshop, and the report will be presented and discussed as part of the Environmental Concerns SWG during the SC meeting.

[1] The purpose, role, operations and impacts from academic seismic surveys will also be considered and discussed.

Importance and timing

The hydrocarbon industry is expanding and accelerating studies to address potential impacts to marine life from sounds associated with offshore seismic surveys.

A significant planning effort by the International Association of Oil and Gas Producers (OGP) is underway to implement a research programme to better understand various technical aspects of potential impacts to marine life.

The first workshop organised by the Joint Industry Project (JIP) on Sound and Marine Life of the OGP on this issue will take place in September 2005.

The IWC 'Seismic Workshop' should occur at SC/58 in order to:

(1) factor in contributions to the JIP process before that process is already completed; and
(2) make priority recommendations to provide information to the IWC and the JIP concerning shortfalls and gaps in scientific knowledge so that the most effective research program can be designed.

With expansion of seismic surveys in the Gulf of Guinea (Smith, 2004) and the regional E&P industry aimed at further discussion on seismic issues, the recommendations from the 'Seismic Workshop' at SC/58 are essential for a second regional E&P industry, OGP, and IAGC meeting. It is essential the SC/58 pre-meeting Workshop takes place before the stated significant expansion of exploration begins.

Statements and Recommendations from SC/56 in 2004

Members of the SWG presented evidence demonstrating specific and growing concerns about exposures to seismic airguns. As a result, the SWG **recommends** that noise remain a priority topic on future SWG agendas.

Last year, the SC noted with great concern (IWC, 2005) the impact on large whales in critical habitats of exposure to seismic sound pulses, particularly with respect to severely threatened populations such as the western gray whale and several breeding grounds for humpback whales.

The potential for effects of sounds or synergy with non-acoustic anthropogenic stressors, as found in other taxa, was recognised and has not been covered in other workshops (but will be covered by the IWC SC/58 pre-meeting).

Given the potential impacts of seismic surveys to cetaceans, as well as the expanded areas of future activity, the SWG had recommended that a Workshop on the impacts of seismic exploration (including both industrial and academic activities) should take place before the 2006 SC meeting.

Terms of Reference

Given the extent of seismic surveys around the world (industry and non-industry) and the concern for impacts on cetaceans at the individual and population levels, the SC needs to inform the Commission of the potential risks to cetaceans, so that science-based management decisions can be made. The initial terms of reference for this Workshop are:

(1) Review and characterise information on seismic sound sources, attenuation and their effects on cetaceans.
(2) Review case studies where ongoing seismic surveys overlap with cetacean distribution in critical habitats and wide-ranging areas (i.e. migratory paths).
(3) Review and evaluate effectiveness of current mitigation and monitoring programs during planning, operational and close-out phases of seismic surveys.
(4) Discuss potential impacts for cetaceans [(1), (2)] and recommended/needed changes in mitigation and monitoring during all phases of seismic surveys [(3)].

Draft Agenda

A series of invited presentations (working titles and authors shown below) and invited and submitted papers will be presented and discussed.

Session I: Review of seismic surveys and potential impacts to cetaceans

(1) Overview of seismic survey sources and need for acquisition and re-acquisition – Jack Caldwell, (Geophysical Contracting Consultant, Houston, TX).
(2) Propagation/attenuation characteristics in relation to ambient noise – Charles Greene (Greenridge Sciences, Inc., Santa Barbara, CA).
(3) Behavioural response in cetaceans to anthropogenic noise with emphasis on seismic surveys – Doug Nowacek (Florida State University, Tallahasse, Florida).
(4) From individuals to populations: evaluating potential cumulative impacts of seismic sources on cetacean reproductive rates – Linda Munson (UC Davis, Davis, CA).
(5) Overview of global seismic surveys (Industry and academia) – John Hildebrand (USCD-Scripps, La Jolla, CA).
(6) Effects on cetaceans at the larger spatial and temporal scales: Seismic surveys in critical habitats and wide-ranging marine environments – Chris Clark (Cornell University, Ithaca, NY).

Session II: Case studies

(1) Western gray whales off Sakhalin Island, Russia – Dave Weller *et al.* (SWFSC, NOAA and others).
(2) Humpback whales and other vulnerable cetaceans in the Gulf of Guinea, West Africa – Ken Findlay (Cetus Projects, South Africa) and Howard C. Rosenbaum (Wildlife Conservation Society, New York).
(3) Migrating bowhead whales in the Beaufort Sea – to be named.

Session III: Science-based approaches to mitigation and monitoring: planning, operation and close-out phases

(1) Current mitigation and monitoring strategies: approaches, strengths and weaknesses – Rob McCauley (Australia).
(2) The need for baseline information on cetacean distribution and role of predictive modelling – Andy Read or Pat Halpin (Duke University, NC).

Session IV: Breakout and discussion groups/recommendations

(1) A critical evaluation of mitigation and monitoring programs and recommended changes.
(2) Implications of seismic surveys (and cumulative noise) on cetacean populations.

Potential solicited papers include, but are not limited to:

(1) Seismic surveys and cetacean distribution off the coast of Brazil.
(2) Review of academic seismic surveys and impacts to cetaceans.

Budget

For eight Invited Participants (assuming Industry support for Caldwell's attendance), the total cost required for the pre-meeting Workshop is estimated at $11,000 USD.

Appendix 4

BUDGET

Total breakdown

IA/E joint total reduced budget (IA and E £30,000 – contribution from each = £15,000)

BRG/E joint total reduced budget (BRG and E £40,000 = contribution from each = £20,000)

E core work IWC SO Collaboration total reduced budget (E £30,000)

Total each sub committee/working group

E = £65,000
IA = £15,000
BRG = £20,000

Table 1

IA, E and BRG joint budget request 2005-2006.

Relevant budget	Recommended budget	Reduced budget		Purpose	Additional information
				Antarctic	
Joint IA/E	£15,000	£8,000	1.	Thiele analysis, ICCED science planning and analysis	Contribution to high priority analysis projects outlined in SC/57/Rep5.
Joint IA/E	£30,000	£20,000	2.	Deakin University – SOC database completion	Complete data entry and validation for IWC Southern Ocean Collaboration Database. High priority task recommended in SC/57/Rep5.
Joint IA/E	0	0		Worby AAD/Ant CRC, Palka + Nicol AAD, Bravington AAD - analysis	Contribution (circumpolar sea ice – whale analysis) to high priority analysis recommended in SC/57/Rep5.
Joint IA/E	£2,000	£2,000	3.	Ensor - analysis	Travel to collaborate on joint analyses (Australia). Contribution (circumpolar sea ice – whale analysis) to high priority analysis recommended in SC/57/Rep5.
Joint IA/E	0	0		Secchi/Dalla Rossa, Thiele, Moore/Reilly	Travel to ODU, Virginia modeling workshop.
	£47,000	**£30,000**		**Joint IA/E Total**	
				Arctic	
Joint BRG/E	£30,000	£25,000	1.	Moore, George, Suydam, (Melnikov), (Haug), Urban, Rojas	Contribution to high priority analysis recommended in SC/57/Rep5. Arctic project 1. Sea Ice - population dynamics.
Joint BRG/E	£20,000	£15,000	2.	George, Suydam, Rowles, Moore, (Melnikov), (Haug), Urban, Rojas, Pamplin	Contribution to high priority analysis projects outlined in SC/57/Rep5. Arctic project 2: Sea Ice - whale health.
	£50,000	**£40,000**		**Joint E/BRG Total**	

Antarctic – Joint E/IA funding

The projects identified at the Sea Ice Symposium for joint E/IA funding were chosen from a much larger list of issues important to the work of the SC. The smaller selection of projects outlined here for funding are: the highest priority, data is available, individuals have been identified who are willing and interested in the analyses and each project can be completed intersessionally.

(1) **£8,000**. Contribution towards analysis by Thiele for high priority projects outlined at Sea Ice Symposium, ICCED science planning and analysis and field co-ordination.
   (i) Thiele is a major data contributor and participant in all of the high priority IA/E joint analysis projects.
   (ii) This is a small amount of funding for the scale of Thiele's contribution to these projects.
   (iii) These analysis projects are unlikely to go ahead without this contribution.

(2) **£20,000**. SOC database completion by Deakin University.
   (i) The database was developed to hold all IWC collaborative cruise data (and other data series previously unavailable).
   (ii) Completion of the database is critical to all of the high priority IA/E joint analysis projects.

(3) **£2,000**. Contribution towards data analysis by Ensor.
   (i) Contribution of data and expertise on sea ice conditions for surveys is critical to interpretation of data in all IA/E modelling projects.
   (ii) The funds are for travel only to meet with collaborative analysis group.
   (iii) Funds for this are low and so this input is critical.

Arctic – Joint BRG/E funding

(1) Sea ice and whale population dynamics: retrospective analyses from basin to fine scales.

(2) Sea ice and whale body condition and health: retrospective data compilation, standardisation and analyses on data from photographic images and whale carcasses.

[*Appendix 4 continued overleaf*]

IWC Southern Ocean Collaboration – E core funding

Table 2
Environment budget request 2005-2006.

Relevant budget	Recommended budget	Reduced budget		Purpose	Additional information
E	£22,000	£18,000	1.	IWC participants for: German SO-GLOBEC (Weddell Sea)	Team of two on two cruises (partial funds for one cruise already allocated from IWC/56 budget).
E	£25,000	£12,000	2.	Thiele cruise coordination, additional database work and ICCED science planning	Logistics, planning, collaboration meetings for field work and analysis with international programs. Data validation, database integration work. Provision of database to Duke-OBIS SEAMAP, sourcing additional data series for database and high priority multidisciplinary analysis/ modeling, analysis of visual and acoustic data.
Total	**£47,000**	**£30,000**			

(1) **£1,800**. SO GLOBEC field work.
   (i) Final two cruises in the SO GLOBEC field effort.
   (ii) Focus is on fine scale repeat surveys and this will be the final two of a three part series of cruises to the same fine scale study site in the Weddell Sea.
   (iii) Important range of seasonal coverage and survey in sea ice of priority for analysis.

(2) **£12,000**. Thiele coordination, analysis, oversee ICCED science planning.
   (i) Thiele has ensured that cetacean studies are a core component of this new multidisciplinary program for the Southern Ocean, we need to stay engaged to ensure we have ship time etc. on this follow on to SO GLOBEC – it will be a long term (at least one decade) program – and this is the sort of data we are missing in analyses – time series of simultaneously collected interdisciplinary data.
   (ii) Ensures our presence in international collaboration in the Antarctic is strong.
   (iii) Conducting and overseeing a number of important spatial analysis projects relevant to the work of SC.
   (iv) Conducting ecosystem modelling with Hofmann and US NSF analyses on circumpolar and predator/ environmental variables.

SOCER
£3,500. Preferred budget and the reduced budget is **£1,800**.

Seismic Workshop
£6,000. Two day pre-meeting to SC/58 to include invited experts to review seismic surveys and the potential impacts on cetaceans, review case studies and science based approaches to mitigation and monitoring.
